In Britain and Europe, aboveground remains undoubtedly formed the basis of most industrial archaeology in the first half century of its existence as a discipline, and the material culture of the workforce, which might have been obtained through systematic excavation, was neglected. The economic historian Walter Minchinton stated confidently in 1983 that "Industrial Archaeology is not primarily about excavation. The aim of industrial archaeologists is to identify structures, buildings and artifacts early enough to ensure their preservation before they are demolished or destroyed" (Minchinton 1983: 125). On the other hand, Donald Hardesty, in his classic *The Archaeology of Mining and Miners*: *A View from the Silver State* (1988), pointed out that so often the standing buildings, machinery, and landscape features characteristic of many British industrial sites did not survive on US mining sites but "they are rich in trash dumps, residential house foundations, privies and other remains of the miners themselves" and that therefore excavation was

Industrial Archaeology, Fig. 3 Suffolk Mill, Lowell, Massachusetts, on one of the many canals which power turbines for water power for cotton manufacture throughout the city. Built in the 1830s by the Suffolk Textile Company, the mill was taken over by the Wannalancit Textile Company but closed in 1981 and is now in use as both university premises and offices

essential. As he suggested, early industrial archaeology concentrated on the technological analysis of specific industrial sites and areas and failed to consider the behavioral aspects of material culture or the processes of culture change. This justifiable criticism began to be remedied in the 1990s and 2000s, when post-processual approaches in archaeological interpretation led to increasing concern with questions of power and inequality, labor relations, and class formation which are central research themes for industrial archaeology, as in Paul Shackel's *Culture Change and the New Technology*: *An Archaeology of the Early American Industrial Era* (1996). This development clearly brought industrial archaeology into a much closer relationship with the existing subdiscipline of historical archaeology, as already practiced in North America and Australasia. In the UK, too, the excavation of industrial sites and the subsequent classification and identification of recovered artifacts has now become standard practice among professional and even many volunteer archaeologists. An article by Palmer and Orange in 2016 contrasted the attitude of historical and industrial archaeologists to industrial sites over a period of 50 years (Palmer and Orange 2016).

Key Issues/Current Debates

Although the discipline of industrial archaeology has developed a great deal over the past two decades, there are still key issues to be resolved. These can be divided into the largely positive and the largely negative, although each impinges on the other.

On the positive side, the debate over whether anything can be learnt from the excavation of industrial sites has been largely resolved and is now part of normal archaeological practice on brownfield sites. There are, though, several problems that distinguish the excavation of historic-period industry from earlier industries and landscapes, namely, the scale of such sites, the formation processes involved, the contamination

encountered, and the presence of standing buildings. The typical large-scale manufacturing processes of the industrial revolution have all left substantial foundations of the process buildings involved, containing, for example, working floors, furnaces, and kiln bases, and substantial foundations for power systems such as wheel pits, engine houses, boilers, and flues. The excavation of such sites frequently produces large quantities of process residues which can be bulk sampled for scientific analysis as part of a program of research that answers questions about the date, origin, and use of such materials and by implication the nature of the activity from the sample area (English Heritage 2018) (Fig. 4). The availability of labor and the arrival of steam-powered and later combustion engine-powered earth-moving machinery meant that many industrial-period manufacturing sites saw extensive earth-moving which radically changed the look of many preindustrial landscapes; often these changes can only be recorded by combining landscape survey data with the excavation evidence. A major health and safety concern on excavations involving historic industries is contamination, and suitable precautions need to be taken as part of a risk assessment. The cost of large-scale excavations of industrial sites is often very high, but even so many city center sites in the UK have been excavated by professional archaeologists, such as the enormous project to record the archaeology affected by the completion of the M74 motorway round Glasgow (Nevell 2016).

One of the outcomes of developer-funded archaeology, however, has been the fragmentation of archaeological study and the consequent lack of synthesis, which is as true for the industrial period as for earlier periods of archaeology. One solution to this in the UK has been the development of both period-based and regional research frameworks which help to establish the significance of sites and set them in some sort of context. The Association for Industrial Archaeology produced such a

Industrial Archaeology, Fig. 4 The man engine and spoil heaps of the Allihies copper mines on the west coast of County Cork in Ireland. The landscape demonstrates the quantity of process residues usually found on such sites which can reveal considerable evidence about the nature of the activity on such sites

research framework which dealt with a range of approaches to the study of industrial sites and structures and also proposed a list of questions which might be considered when such sites are treated archaeologically, to help further our understanding of the process of industrialization (Gwyn and Palmer 2005). The Historical Metallurgy Society followed with a research framework in 2008 (Bayley et al. 2008). Such research frameworks help to combat the tendency among industrial archaeologists to interpret sites in terms of technological paradigms and encourage them to see their sites in a wider context, both nationally and internationally.

One of the negative issues on a global front is a decline in new entrants into work on industrial archaeology, even in the UK where the industrial heritage is generally recognized as a key element of Britain's contribution to world culture. Many university-based archaeology courses now include some industrial archaeology, usually under the broader term of historical archaeology, but there are few staff members who have the necessary knowledge to acquaint students with the fundamental principles of the discipline. Even at the postgraduate level, there are few courses available. The pioneering master's degree course at the Ironbridge Institute in the UK, now based in the University of Birmingham, concentrates more on general heritage management. The Master of Science in Industrial Archaeology at Michigan Technological University in the USA is one of the very few which trains students in the archaeology of industrial sites, while the Institute of Industrial Archaeology, History of Science and Technology at the German Technical Museum of Freiburg concentrates more on the aboveground structures in its bachelors' and masters' courses. Professional archaeologists in most areas have, therefore, to develop the skills necessary for industrial archaeology in the course of their working lives, or through distance learning or continuous professional development courses, which remain few in number.

Finally, standing structures are frequently found on industrial sites, and the study and understanding of the buildings of industry have formed a central feature of industrial archaeology since the inception of the subject. Since industrial buildings and process structures tend to be spread over a large area, it is necessary at the outset to identify the types of buildings surviving on a site and to prioritize the recording appropriately. It is important to be able to recognize the significant features of industrial buildings which indicate their past functions as well as the remains of the long-gone fixtures and fittings (Richards 1958). As in the case of excavation of industrial sites, this is an acquired skill for which training is needed and the Council for British Archaeology's *Industrial Archaeology: A Practical Handbook* provides a helpful guide (Palmer et al. 2012). However, traditional industries continue to contract, and the future for many of these buildings lies in their adaptive reuse. Large industrial buildings are particularly difficult to adapt for modern purposes, while the sheer scale of some historic industrial processes, such as mining, quarrying, and mass production, can be a conservation challenge in itself. In England, English Heritage identified the industrial heritage as the theme for its 2011 Heritage at Risk program, pointing out that nearly 11% of grade I and II∗ industrial buildings are at risk, far higher than the 3% of grade I and II∗ buildings of other types which are at risk in England (English Heritage 2011). The high costs of conversion and, in some cases, decontamination remain a deterrent to many developers, particularly if the buildings are in areas of low property values. Nevertheless, there are many examples of successful reuse around the world, even such difficult sites as iron furnace complexes at Sloss in Birmingham, Alabama, USA, and Duisberg in the Ruhr district of Germany. Where adaptive reuse proves impossible, then preservation by record remains the only option, and it is essential to ensure that this is done before demolition.

International Perspectives

In 1983, the journal *World Archaeology* devoted a volume to industrial archaeology (Vol. 15. No. 2, 1983). In his overall survey of world industrial archaeology, Minchinton suggested that industrial archaeology had been one of the more

successful British postwar exports but that he hoped that a similar survey in 10 years' time would be able to report on a more extensive geographical activity, a widened topical scope, and a greater professionalism in industrial archaeology throughout the world (Minchinton 1983: 134). On the whole, these three objectives have been achieved. The Web site of the International Committee for the Conservation of the Industrial Heritage, TICCIH, founded in 1978, includes a list of those countries undertaking recording of the industrial heritage. For example, the Society for Industrial Archaeology in the USA, formed in 1971, and the Association for Industrial Archaeology in the UK, dating from 1973, both seek to promote the study and practice of industrial archaeology, as do the *Comité d'information et de liaison et de promotion de l'archéologie industrielle* (CILAC) in France, founded in 1978, and the *Asociación Vasca de Patrimonio Industrial y Obra Pública* (*AVPIOP*) in Spain, founded in 1984. The narrow concentration on the archaeology of production which marked the early years of industrial archaeology has been considerably widened to include the archaeology of consumption, with consideration of the significance, use, and distribution of the artifacts of the period as well as the social context of their manufacture. Finally, as suggested earlier, the rapid decline of traditional industry, especially in the western hemisphere, has led to a far greater participation by professional archaeologists on historic-period industrial sites, especially in the context of developer-funded archaeological excavation. However, individual countries tend to concentrate on their own particular sites and products, and more comparative studies are needed to explore the importance of technology transfer and the impact of global trade (Palmer and Neaverson 2000) (Fig. 5). TICCIH, as the

Industrial Archaeology, Fig. 5 Linares in the Andalusian province of Jaén in Spain became an important center in the nineteenth century for the mining and smelting of lead. The Cornish engine houses on this site of La Tortilla demonstrate the transfer of mining technology, which was replicated in many other parts of the world

recognized advisor to ICOMOS on industrial heritage, could do more to facilitate this. The Nizhny Tagil Charter, passed by the assembled delegates at the triennial National Assembly of TICCIH held in Moscow on July 17, 2003, concentrates more on industrial heritage than the comparative study of industrial archaeology, which is anyway necessary for site interpretation (Nizhny Tagil Charter 2003). TICCIH has also widened its scope to recognize the differences from Europe in the physical manifestations of industrialization and industrial heritage of Asia, expressed in the Taipei Declaration for Asian Industrial Heritage (Taipei Declaration 2012).

The international value of the industrial heritage has also been recognized through the designation by the United Nations Educational, Scientific and Cultural Organization (UNESCO) of more than 60 World Heritage Sites since 1978 whose significance is mainly industrial. The distribution of these on a global basis is uneven, depending on when specific countries became members of UNESCO or, in some cases, withdrew from the organization for political reasons; the USA was not a member from 1985 to 2003, for example. The sites range from Røros Mining Town in Norway, inscribed in 1980; the Ironbridge Gorge in the UK, including the world's first iron bridge of 1779 (Fig. 6), which was inscribed in the first tranche of UK World Heritage Sites in 1986; the UK's pioneering textile sites of the Derwent Valley, New Lanark, and Saltaire in 2001; the Humberstone and Santa Laura Saltpeter Works in the Atacama desert of Chile, inscribed in 2005; the Iwami Ginzan Silver Mine and its cultural landscape in Japan in 2008; and the Erzgebirge/Krušnohoří Mining Region, inscribed in 2019. The pace of such designations has decreased in

Industrial Archaeology, Fig. 6 The Ironbridge across the Severn Gorge in Shropshire, the world's first iron bridge, cast in Abraham Darby's Coalbrookdale foundry in 1777 and erected in 1779. Now in the care of English Heritage, the bridge was originally saved by the Ironbridge Gorge Museum Trust and is the centerpiece of an industrial landscape accorded World Heritage status in 1986

recent years with the recognition of the need to ensure adequate management of inscribed sites, especially industrial ones, where the balance between heritage value and modern redevelopment is often difficult to maintain.

Future Directions

Industrial archaeology has been extremely successful in achieving what its pioneers set out to do – achieve recognition for the importance of the remains of the industrial past and where possible their survival in the contemporary landscape. Nevertheless, as the 2011 English Heritage "Industrial Heritage at Risk" initiative has shown, the industrial heritage remains at risk from many quarters, not just neglect and redevelopment. The global recession has led to massive funding cuts which impact on archaeological services, and it is not clear how far current levels of protection for archaeological sites within the planning process will be maintained.

Nevertheless, the discipline has matured in the half century of its existence, moving away from technologically dominated explanations of the remains of the industrial past toward a greater concentration on the social context of industrialization, with, for example, studies of workers' housing and the spatial analysis of mills and factories to try to understand how people and machines functioned as a whole (Fig. 7). Studies of industrial landscapes have explored ways in which these not only manifest the physical remains of industrial processes but also embody evidence for past hierarchical power relations in the layout of settlements. The dawn of a new century has also led to a greater interest in the

Industrial Archaeology, Fig. 7 Blind-back housing in the Kartuizerlaan beluik in Ghent, Belgium. Built as workers' housing in between cotton mills in the nineteenth century, many of the beluiks have been adapted for modern gated housing

Industrial Archaeology, Fig. 8 Pozo n° 5 at La Reunión, a coalmine worked in the past by the railway company MZA (Madrid-Zaragoza-Alicante) and located in Villanueva del Río y Minas in the province of Seville, Andalucía. The ornamental tower is an electricity generating station dating from 1926. The site is listed as "Bien de Interés Cultural," the highest category in Spain, but there is currently no conservation being undertaken

industrial remains of the twentieth century, particularly in countries where industrialization came rather later than in the UK where concern for the eighteenth-century structures dominated the early years of the discipline.

Nevertheless, industrial archaeology remains a discipline in tension, which seeks to maintain a balance between investigative archaeological techniques which can lead to destruction of sites and the preservation of sites and structures for posterity (Fig. 8). It will doubtless continue to do so, and its vigor lies in both the continuing participation of volunteer activists like those who saved industrial sites in the middle of the twentieth century and valuable work of professionals who have increasingly undertaken recording and excavation of industrial sites as part of their normal routine.

Industrial Archaeology, Australia

Aedeen Cremin
Yass, NSW, Australia

Introduction

Since colonization in 1788, the Australian continent has been part of the global economy. Industry has left substantial traces in the landscape, deforestation, infrastructures, and industry-specific artifacts, some of which have been archaeologically investigated. Archaeological research is usually undertaken as part of heritage management plans or as part of large-scale development, especially in the mining industry.

This entry discusses industries created between 1788 and 1901, excluding defense.

Definition

Industrial archaeology deals with the material remnants of an organized system of labor and its people. Industry has been a major component of

Australia's settler history, and there are significant remains, some of which have been investigated archaeologically.

Historical Background

Academic Teaching and Publishing

Industrial archaeology was at first a fieldwork exercise for external or undergraduate students and did not become an academic discipline – under the rubric "historical archaeology" – until the 1970s. It is now widely taught, still as part of historical archaeology, because the two cannot be dissociated given the importance of industry to Australia's settler history (Connah 1993). Academic theses often deal with specific sites or processes, and much of that research is published in *Australasian Historical Archaeology* established in 1983 (AHA, online, indexed) or in the *Journal of Australasian Mining History*, established in 2003 (JAMH, online). Researchers also publish internationally (e.g., Stuart 2013).

Corporate Work

Australia has several specialist consulting firms with well-qualified personnel. They usually undertake archaeological investigation as part of a heritage listing – at national, state, or local level. Many projects include parallel studies of Indigenous and settler sites. Reports are part of the listing and may be available on the relevant authority's website (e.g., Vines and Yugovic 2011; Bell 1995). Consultant reports for private firms are often confidential, but parts may be published in academic journals.

Sites of national significance are listed on the National Heritage List (NHL, online) which gives full details and references. Significant engineering heritage is recognized by Engineers Australia (EHRP, online).

Australia's Industrial Development

Britain's colonization of Australia was part of a larger, global enterprise. The penal colonies (1788–1869) operated on an industrial basis from the start, insofar as all aspects of life were controlled by the state, acting as an employer. Manufacturing was not encouraged, and any useful raw materials were to be processed in Britain. Industrial processes were minimal and most work was still done by hand. Convicts built roads and harbors, made bricks, felled timber, and operated coal mines in the first stages of settlement (Gojak 2001).

By the 1830s many convicts had served their jail time but were still stranded in an environment very different from their homelands. The settler population now included former British military personnel and free emigrants, some of whom had come to join convict relatives, others to escape grinding poverty in Britain and Ireland. All of these people applied for grants of land from the colonial government. There was a general and unjustified feeling of optimism. The settlers were encountering unknown conditions and, disastrously, did not understand about the climatic effects of the El-Niño Southern Oscillation (ENSO), which may cause severe and prolonged droughts. As a result, much of the nineteenth and early twentieth centuries were periods of agricultural boom-and-bust.

Pastoralism: Sheep, Cattle, and Camels

By the 1820s there had been substantial exploration of the southeastern coastal areas, and it had become obvious that much of its hinterland could feed domesticated livestock. This was the start of what would become a key industry: wool production. Enormous tracts of land were given to entrepreneurs, such as the Australian Agricultural Co., granted 1 million acres in 1824 in New South Wales (NSW), or the Van Diemens Land Co., granted 250,000 acres in 1825 in what is now Tasmania (Tas). Other pastoralists, the "squatters," simply seized land. The effect on the Indigenous population was disastrous, with destruction of habitat, dispossession, thefts of women, and massacres (e.g., Myall Creek, NSW, see Lydon and Ryan 2018). Successive governments generally ignored these crimes, and impunity remained the norm well into the twentieth century, as wool was so profitable and developed so rapidly: Australia's exports rose from 8000 bales in 1830 to 137,000 in 1850. Sheep numbers rose from 1 million in 1830 to an all-time high of 85 million

in 1890, by which time much of the continent had been opened up for stock raising.

From an archaeological point of view, there are two salient characteristics of pastoralism: changes in the landscape and the development of a layout for sheep "stations," including paddocks, shearing sheds, men's quarters, and an owner's or manager's "homestead." These structures were usually made of wood and recycled as required, so that few stations are still in their original condition. They are, however, well documented through business records, images, newspaper articles, and personal recollections, e.g., the Brickendon Estate, Tas, now on the National Heritage List (NHL).

Cattle pastoralism followed sheep pastoralism in much the same areas where appropriate fodder and water were available; however, meat was not exportable until the development of suitable refrigeration techniques in the 1880s. At around the same time, it became possible to sink "bores" into the aquifer – the Great Artesian Basin, c. 65,000 km^2 – which underlies about one fifth of Australia's landmass. Groundwater is pumped up through metal windmills which are now one of the most distinctive features of pastoral stations. Four thousand seven hundred bores are said to have been drilled, enabling a massive expansion of cattle-raising, which today is still concentrated over the Basin, and supporting up to 16 million head of a total herd of 26 million.

The layout of a cattle station is very similar to that of a sheep station. Both covered a lot of land, and the animals were managed by stockmen who had to be proficient on horseback, so an ancillary form of pastoralism was that of horse breeding. The "Walers" – horses crossbred in New South Wales – proved to be good cavalry mounts and were supplied to the British forces in India for almost a century (1840s–1930s). Stock horses were similar to the Walers and many were taken by their owners to serve in World War I. The stockman has been mythologized almost as much as American cowboys and gauchos and is now celebrated in the Stockman's Hall of Fame at Longreach, Queensland (Qld).

Camels were used as pack-animals in the arid zones of central and Western Australia. They were introduced in the 1860s, along with their handlers, usually referred to as "Afghans." Over time camels were more widely used, and between 1906 and 1910 they were employed by the government of Western Australia (WA) in an ambitious though ultimately useless project, the Canning Stock Route (CSR). The CSR, named after its surveyor, was an 8 km-wide track driven through desert to bring livestock 1770 km from northern WA properties to the southern markets. The industrial remains are those of the track itself and of wells and troughs sunk at regular intervals (Grimwade 1998; Bianchi 2013). As local Indigenous people were coerced into giving information about finding water, the heritage-listed route also has a substantial Indigenous history.

Pastoralism required a significant amount of seasonal labor, for fencing, mustering, shearing, and moving stock. Much of this labor was supplied by itinerant workers, moving from station to station, where they were housed, fed, and paid. Disputes over wages, especially for shearing, led to the formation of unions and a major strike in 1891, when 4500 workers gathered at Barcaldine, Qld (Egloff et al. 1991). However, in northern and Western Australia, much of the work was done by local Indigenous people, living in camps where they were given minimal supplies of tea, flour, and sugar, but had neither wages nor civil rights (Morgan 1989). These conditions prevailed until the 1960s when Indigenous workers took political action by walking off the stations (NHL, under Wave Hill Walk-Off). This was the start of an Australia-wide change of policy toward Indigenous people.

Food Production

Although much of Australia's land area, 762 million hectares, is arid or dry land, there is abundant rainfall along the eastern and southeastern coasts, and, overall, about 200 million hectares are suitable for cultivation. Given that the climate zones range from tropical to cool temperate, those areas can produce a wide variety of food, and today Australia exports wheat, raw sugar, wine, fruit, and dairy products. Wheat is produced through rain-fed agriculture in the "sheep-wheat belt" where seasonally fallow land serves as pasture

for sheep. Today these areas carry over two-thirds of the total flock of 72 million sheep.

Food production is inevitably localized, and most regions will have their own specialized sites, museums, or heritage trails. Few have been investigated archaeologically, but the potential is there, as food industries have developed in situ and retained traces of their past. Cheese, for instance, has been made at Bega in southeastern NSW since the 1860s, while wine has been produced in the Hunter Valley, in NSW, since the 1820s and in the Barossa Valley in South Australia (SA) since the 1850s. A report on Tasmania's apple industry, which has operated since the 1830s, identified 2000 places, of which 446 have survived (McConnell and Servant 1999). Breweries were created in the larger towns, and many of their buildings have been retained.

Some industries are well documented historically but understudied archaeologically. This is particularly true of the Queensland sugar plantations which were worked by indentured Pacific Islanders from 1860 to 1900. Substantial relics include a kilometer-long causeway, manually constructed in 1884, at Habana, near Mackay, and a small stretch of the much longer Sugar Wagon Trail, also built in 1884, to bring sugar from the Yeppoon Mill to the coast near Rockhampton over 45 km away.

Communications

Railways have been keys to Australia's industrial development, since so much production was intended for export. Stock could be walked ("droved") to the ports, but it was impracticable to transport large quantities of wool, wheat, or flour by bullock cart. Accordingly, the early railways mirrored the pattern of pastoral and mining development and, regrettably, of colonial rivalries, each colony determining its own routes and gauges, a situation which was not normalized until the 1970s (Cremin 2001: 62–63). Equipment was imported from Britain. In the wheat belt, the railway stations are flanked by flourmills, generally quite substantial buildings. The railways enabled small towns to survive, and today many of these towns have railway preservation societies which maintain both tracks and engines. City railway stations were monuments of civic pride, and are all conserved, some with innovative remodeling, such as the Eveleigh Carriage Works in Sydney (1888–1989) which has been repurposed into a cultural venue.

An important development for colonial Australia was the Overland Telegraph which enabled it to communicate with Britain. It ran north 3178 km from Port Augusta, SA, to Darwin, right through the deserts of central Australia, with repeater stations every 120 km (Cremin 2001: 10–12). At the newly created settlement of Darwin (then called Palmerston), it linked up with a submarine system going via Indonesia and India to Suez. Built in 26 months, it was an astonishing achievement which enabled politicians and investors in Britain to keep track of Australian developments. At a humbler level, it also provided some services to isolated communities. In 1877 it was supplemented by one running across the Nullarbor between South and Western Australia, which in 1889 ran its own line from Perth to Java via Broome (EHRP, under Broome Court House).

Maritime Industries

As an island colony, eighteenth and nineteenth century Australia was totally dependent upon sea traffic, which was supposedly regulated by Britain. However, American and French ships could avoid whatever regulations were in place, and in practice there was quite a lot of non-British presence in Australian waters. Locally built ships carried the coastal trade. All colonial (now state) capitals were close to the coast, with ports that had appropriate harbor, revictualling, and storage facilities, wool warehouses being particularly impressive buildings. The oldest and best-studied harbor is that of Sydney, which was created in 1788 (Kelly 1997; Johnson and Parris 2008) and has managed to preserve many traces of the convict period around Sydney Cove. Hobart, Tas, was founded in 1803 and Darwin, NT, in 1870.

The other capitals, Adelaide, SA, Brisbane, Qld, Melbourne, Vic. and Perth, WA, were on rivers some kilometers inland. A convict settlement was created in 1823 at Moreton Bay, which served as port for Brisbane; Fremantle Port and Perth town were created together in 1829, and

Port Adelaide was created in 1836, but Melbourne, which had been settled overland rather than by sea, did not get a seaport until 1877. All of these places contain substantial heritage items and museums. There were few inland ports, but the one at Echuca, Vic, was vital to the wool trade, with wool carried on paddle steamers. It operated between 1867 and the 1880s when the railways took over (NHL, under Echuca Wharf).

Whaling and sealing were important industries throughout the nineteenth century and have been very well studied (Lawrence and Staniforth 1998; Paterson 2006). A less well-known industry, but longer-lasting, has been pearling, carried out all along the northern coasts since the 1860s. The first divers were unpaid Indigenous people with some indentured labor from the Pacific and Indonesia, but after the 1880s the industry employed Japanese and Chinese deep-sea divers (Edwards and Yu 2018). It has been largely responsible for the growth of Broome, WA.

Mining

Mining, both Indigenous and immigrant, is by far the most studied aspect of Australian industrial archaeology. Mine shafts for extracting silica were dug into Koonalda Cave, SA, over 20,000 years ago (NHL under Koonalda), and there is a millennia-long tradition of Indigenous ochre mining (NHL, under Wilgie Mia Ochre Mine; Sagona 1994). Colonial mining started in 1796 with the discovery of coal in the Hunter Valley of New South Wales – presciently named by Captain James Cook in the 1770s. The convict establishment at Newcastle, NSW, exported coal to British India and is still a major coal port. The first metal ores were found in South Australia, silver-lead (1841) and, more significantly, copper from 1843 which enabled the colony to survive, with an influx of copper miners from Cornwall, led by their "captains" (NHL, under Australian Cornish Mining Sites). The next breakthrough was the discovery of gold in 1851 in both NSW and Victoria, precipitating "rushes" that effectively peopled Australia. Victoria's population went from 10,000 in 1840 to 500,000 in 1860. The new immigrants came from all walks of life, from dockworkers to lawyers, and started to assert civil rights which up till then had been strictly controlled by Britain (NHL, under Eureka Stockade Gardens).

The colonies now had economic clout, as the hunt for minerals spread across the continent in a "rush that never ended" (Blainey 2003). Silver was discovered on pastoral stations in the extreme west of NSW at Silverton in 1881, and in 1883 at Broken Hill, which is said to have one of the world's largest deposits of zinc and lead (NHL, under City of Broken Hill). A public company was formed in 1885 (now BHP Billiton), but there were problems with processing sulfide ores that were not resolved until 1903. The discovery of gold at Kalgoorlie, WA (1893), opened up a hitherto underpopulated region of southeastern Western Australia. A major spin-off from that was the construction between 1896 and 1903 of a 560 km-long pipeline bringing water from Mundaring Weir, near Perth (NHL, under Goldfields Water Supply Scheme). Opal was picked up around the Great Artesian Basin region from the 1880s, but not effectively mined until the 1910s.

From the archaeological point of view, there are mining remains almost everywhere in rural Australia. Ghost towns are numerous though not usually spectacular, as everything portable has been removed –some are now within national parks, e.g., Mt. Alexander, Vic. or Hill End, NSW. Other mines are being reworked, e.g., Cadia, NSW. There are also substantial remains of the early attempts at ironmaking, which culminated in the creation of the first steelworks at the coal town of Lithgow, NSW, in 1901 (Jack and Cremin 1994).

The sudden wealth brought about by mining had an enormous effect on social life. Government control ensured the creation of reasonably ordered towns to which mineral seekers were encouraged to bring their families (e.g., Lawrence 2005). However, increased Chinese immigration caused conflict, resulting in the infamous White Australia Policy (1901–1973). Optimism in the mining and allied industries led to confident and strong popular movements, especially at Broken Hill and Kalgoorlie. All of this hastened the rise of self-government, eventually leading to the Federation of the various colonies into the Commonwealth of Australia in 1901 (Cremin 2001).

Key Issues/Current Debate

The perennial problem is the cost of industrial archaeology. Few institutions want to invest in it, unless forced to do so by heritage legislation. There are also negative views of industry, particularly if it was dangerous or dirty. Attitudes can be changed but it takes time, which most archaeologists don't have. However, the booming interest in both local and family histories means that many Australians, including Indigenous people, find a personal resonance in private research on specific places and processes.

International Perspectives

Australia's industrial archaeology is well within international norms. Because of Australia's entangled Indigenous and immigrant histories and also its "dark" past as a penal colony, it has been innovative in the recognition of the social effects of industrialization and also in an understanding of globalization. However, it has paid relatively little attention to the environmental effects of industry.

Future Directions

Australian industrial archaeology will become more global, and it is likely there will be more comparative research into similar colonial societies, such as Argentina, South Africa, or Siberia. There will be more research into the history of minority groups involved in the various industries and, perhaps, some reflection on modern industry's role in the Anthropocene.

Industrial Heritage Association of Ireland (IHAI)

Ronald Cox
Industrial Heritage Association of Ireland, Dublin, Ireland

Basic Information

The present Association was formed in 1997, although there had been a similar grouping of persons with an interest in industrial heritage operating in the 1970s. The focus of the Association is based on making the general public more aware of their industrial heritage, of assisting them in understanding the importance to future generations of conservation, preservation, survey, and identification of important sites, and to this end aims to recruit members and identify those who would actively participate and inform on industrial heritage throughout the island of Ireland. The Association was incorporated into a limited liability company in 2005. An Executive Committee, comprising the Officers of the Association (president (Brendan Delany in 2013), vice-president, secretary, and honorary treasurer) and up to ten ordinary members, elected by members at the Annual General Meeting is responsible for administration of the Association and its affairs.

Major Impact

Since the Association was formed, it has organized excursions to industrial heritage sites, and its members have conducted surveys and contributed through a regular newsletter to matters of industrial interest. Its members are provided with a forum on its website www.ihai.ie to enable them to discuss industrial heritage matters, and various papers have been written by members and those associated with industrial archaeology and presented at conferences held at irregular intervals (see Further Reading).

The Association held an important Networking Conference in conjunction with the Heritage Council, which was held at Dublin Castle in November 2006. In this the Environment and Heritage Service (Northern Ireland) and the Office of Public Works participated. The results of the Conference have provided some understanding in government circles of Ireland's industrial heritage and its importance in tourism and in cross border connections. A Working Heritage Report was adopted by the Heritage Council, but regrettably the report has not yet been acted upon to any significant extent.

The issues which emanated from this Report constitute some of the current aspects that are so

important for further progress towards an assimilation of the subject by responsible bodies:

- Raise awareness of the work done by many groups and agencies.
- Promote an integrated approach to the conservation of industrial heritage.
- Involve all parties in debate, discussion, and policy formation.
- Identify the main issues facing the sector.
- Encourage a survey of industrial heritage, to add to the Northern Ireland survey.
- Become an umbrella to represent the sector, be a channel for enquiry, and be a referral point.

The Association has enlarged its membership and widened its publicity towards representation on industrial heritage. It now, with the help of other interested parties, plans to provide a platform for industrial archaeological studies in conjunction with leading technological companies, who are aware of the importance of the past that made their future possible, and are prepared to address and support the Association's activities.

In today's world new technology becomes old even more quickly, and the Association intends to continue to archive material from past industries.

Industrial Heritage in Archaeology

Bode Morin
Anthracite Heritage Museum and Eckley Miners' Village, Pennsylvania Historical and Museum Commission, Scranton, PA, USA

Introduction and Definition

Industrial heritage in the simplest sense is the aggregate remains of industrial societies. In practice, it is the study and/or reuse of these remains. Industrial heritage encompasses a broad array of objects, structures, landscapes, and historical practices including all of the social and material culture directly or indirectly related to the people engaged in the production and management of infrastructure and transportation and the production and distribution of raw materials, objects, and energy. While the industrial heritage is manifest in specific things, this heritage is primarily engaged for study and documentation, conservation, and commemoration. Industrial archaeology (IA) is the study and documentation of this social and material culture and is generally administered by historians and archaeologists specifically trained to access industrial heritage and industrial landscapes. Conservation relies on the work of industrial archaeologists but incorporates issues of value and significance to determine the long-term consequences of industrial places often balancing value with environmental risks and the adaptability and market value of conserved places. Conservation practitioners include

architects, historic architects, engineers, historians, curators, educators, conservators, property developers, government promoters, financiers, and potential end users. Commemoration is the public celebration, interpretation, or acknowledgement of significant things, places, or events be they of local importance or demonstrating outstanding universal value and eligible for world heritage nomination. Commemoration includes memorial plaques, museums, festivals, and more personal pursuits like art, photography, and urban exploration. Commemoration has implications for identity on the local level and tourism and economic redevelopment in the case of regional, national, or world heritage.

The International Committee for the Conservation of the Industrial Heritage (TICCIH), the body designated to advise the International Council on Monuments and Sites (ICOMOS) on industrial heritage, defined the field as:

> *Industrial heritage* consists of the remains of industrial culture which are of historical, technological, social, architectural, or scientific value. These remains consist of buildings and machinery; workshops; mills; factories; mines and sites for processing and refining; warehouses and stores; places where energy is generated, transmitted, and used; transport and all its infrastructure; as well as places used for social activities related to industry such as housing, religious worship, or education.
> *Industrial archaeology* is an interdisciplinary method of studying all the evidence, material and immaterial, documents, artifacts, stratigraphy and structures, human settlements, and natural and urban landscapes, created for or by industrial processes. It makes use of those methods of investigation that are most suitable to increase understanding of the industrial past and present.
> The *historical period* of principal interest extends forward from the beginning of the Industrial Revolution in the second half of the eighteenth century up to and including the present day while also examining its earlier pre-industrial and proto-industrial roots. In addition, it draws on the study of work and working techniques encompassed by the history of technology (TICCIH 2003).

Historical Background

The roots of industrial heritage (IH) started with the recognition of value in what had been overlooked industrial landscapes. At the core of IH was the understanding that from the 1750s, profound technological, social, and economic changes spread across Britain ultimately altering the fabric of life, the environment, and the physical and financial well-being of vast number of people. This change, highlighted by the reorganization of power, production, technology, and labor, became known as the Industrial Revolution which was distinctly British at its start but quickly spread across the world. While the debate continues as to whether the Industrial Revolution was actually revolutionary or whether it truly began in the 1750s, the mid-eighteenth century was the point that the physical industrial record became more prominent and cultural changes, which continued to have a profound impact into the twenty-first century, came more rapidly.

The field began with the formation of a practice, industrial archaeology (IA), in Britain in the 1950s. Like other archaeological and historical disciplines, IA began as an amateur pursuit led by interested individuals. Its early advocates reacted to dramatic changes in the 1950s British landscape and the loss of industrial material culture as new, postwar demolition and construction encroached on former industrial areas heretofore not considered significant. Key structures were being demolished with little consideration or reverence for their actual significance to British history. Public reaction grew from these dramatic landscape changes and led to stronger identification, recognition, and protection programs for the extant material evidence of this clearly definable economic era. Neil Cossons, former director of Ironbridge Gorge Museum Trust and later chair of English Heritage, wrote in the revised second edition of the *BP Guide to Industrial Archaeology* (originally published in 1975) that "IA was born, not out of a detached or academic interest but on a

wave of emotional enthusiasm and a less defined but clearly deep-seated feeling that a vital part of the past was being destroyed.. .The postwar years, dominated with a preoccupation with renewal and a new foundation for future prosperity, saw the destruction of much that was old" (Cossons 1987: 11).

By 1979, Kenneth Hudson, a former BBC correspondent who wrote several works on industrial heritage including the seminal publication *Introduction to Industrial Archaeology* (1963), stated that IA had evolved through three developmental phases. Stage one, he wrote, was the formation period in the 1950s bringing the plight of industrial heritage to the attention of a wide audience. Stage two, which lasted through the 1960s and into 1970s, entailed a sizable portion of volunteers, initially in Britain, identifying extant heritage and creating national lists with an emphasis on buildings and machinery. Stage two also witnessed IA spread to other industrial countries across the world. Stage three, Hudson argued, developed from the realization that there was an enormous collection of data generated in stage two in need of a more structured analysis (Hudson 1979: 2–3).

By the 1970s, a professional discipline was formalizing. In 1969, the US National Park Service created the Historic American Engineering Record to formally document significant industrial and engineering works in the United States and maintain those records in a long-term archival format in the Library of Congress (see Figs. 1 and 2). In 1971, a dedicated group of US archaeologists, museum curators, engineers, and historians met in Washington, D.C., and established the Society for Industrial Archeology (SIA) to "promote the study,

Industrial Heritage in Archaeology, Fig. 1 Typical HAER architectural rendering of an industrial process showing the "Gray Iron process c. 1947" at Stockham Valves and Fittings foundry in Birmingham, Alabama. (Delineator Christen Peterson, 1994. US National Park Service, Historic American Engineering Record)

Industrial Heritage in Archaeology, Fig. 2 HAER image of Stockham Valves and Fitting foundry in Birmingham, Alabama, titled "Interior View with Iron Pourers Filling Completed Molds on Grey Iron unit No. 1 Mold Conveyor." appreciation, and preservation of the physical survivals of our industrial and technological past" (SIA n.d.). Its mission would be:

> to encourage the study, interpretation, and preservation of historically significant industrial sites, structures, artifacts, and technology. By providing a forum for the discussion and exchange of information, the Society advances an awareness and appreciation of the value of preserving our industrial heritage. (SIA n.d.)

In 1969, the Council of British Archaeology proposed forming a national society made up of the smaller clubs documenting industrial sites. In 1973, they formed the Association for Industrial Archaeology to "sponsor research and reward excellence, pool knowledge and set standards of recording, encourage research and publication and assist preservation through a restoration grants programme" (AIA 2015). The organization expanded its mission to support conservation by monitoring applications for industrial site demolition or modification. Other national groups followed including the Japan Industrial Archaeology Society (1977) and Comité d'Information et de Liaison pour l'Archéologie, l'Étude et la Mise en Valeur du Patrimoine Industriel (CILAC) in France (1979).

On the global stage, the International Congress on the Conservation of Industrial Monuments formed at a meeting held in Ironbridge (UK) in 1973 and started holding triennial congresses focusing on international issues. In 1978, the group renamed itself the International Committee for the Conservation of the Industrial Heritage (TICCIH), which, in 2000, entered into a formal agreement with the International Council on Monuments and Sites (ICOMOS) to consult on industrial world heritage nominations and promote industrial heritage conservation (ICOMOS and TICCIH 2000). TICCIH:

> is the international organisation for industrial archaeology and the industrial heritage. Its aim is to study, protect, conserve and explain the remains of industrialization (TICCIH n.d.). [TICCIH was] established for the primary purpose of achieving cooperation at an international level in the preservation of industrial monuments and artefacts and in fostering an understanding between nations of the historical, scientific and educational value of mankind's industrial heritage. (ICOMOS and TICCIH 2000)

During Hudson's third stage in the 1980s and early 1990s, IA became a more codified practice with the creation of academic programs in industrial archaeology at Rensselaer Polytechnic Institute (NY), University of Birmingham's Ironbridge Gorge Institute (UK), West Virginia University (WV), Michigan Technological University (MI), and later programs in Leicester (UK) and Manchester (UK) universities. These programs, led by academics working in and continually defining (and redefining) the field, began incorporating

more anthropological themes asking critical questions about places, practices, and industrialization's effects on human conditions. These programs also provided specialized training to new professionals entering the field and those working in cultural resource management who may encounter industrial heritage. Neil Cossons wrote in 1987, demonstrating that IA was evolving a much more rigorous approach to understanding industrial heritage, that:

> Industrial archaeology is a cultural archaeology, the study of the culture in which industry has been dominant and in particular its physical manifestations and the light they shed upon our understanding of industrial society. (Cossons 1987: 10)

In the 1990s, the field of industrial heritage expanded with a newer focus on conservation and commemoration. If Hudson's first, second, and third phases of industrial archaeology focused on identification and study, the new focus, the fourth phase, attempted to answer the question: How do we preserve and integrate these places culturally? The preservation of industrial heritage was not new in the 1990s. In 1925, one of the first industrial museums in the United States opened at Old Slater Mill, in Pawtucket, Rhode Island. Owners of the historic Cornwall Iron Works donated the monument to the Commonwealth of Pennsylvania in 1932, and the Henry Ford Museum (Dearborn, Michigan) of industry and technology opened to the public in 1933. The US National Park Service reconstructed Saugus Iron Works National Historic Site (Saugus, Massachusetts) in the 1950s after extensive archaeological excavations that began in the 1940s. The Iron Bridge Gorge Museum Trust (Shropshire, GB) was formed in 1967, Eckley Miners Village (Weatherly, Pennsylvania) was preserved in 1971, and the 100-year-old Birmingham, Alabama, blast furnace complex, Sloss Furnaces, became a historic site in 1971.

While these key places had been preserved because of their significance and became important museums and historic sites, the 1990s saw a greater focus on economic regeneration and reaching broader audiences. The western world had been completely transformed by industry which created huge collections of buildings and completely altered landscapes – not all of which were significant. Further, western industrial decline began in the 1950s with key industries witnessing significant declines in the 1980s and left behind "rust belt" cities with aging populations and limited prospects for new economic development. While this triggered and sustained the academic side of IH, it also left behind devalued landscapes and souring economies with increasing interest in conservation and reuse, tourism, and economic regeneration as salves to spur new development and lure tourist dollars.

From the 1980s to the 2000s, adaptive reuse of former industrial sites became a popular and economically attractive means to conserve large sites and appeal to a broad, less historically inclined audience. The Sloss Furnaces development included a stage in one of its former cast sheds for concerts and maintains an active arts and festival program. The former extensive Bethlehem Steel plant (PA) has been redeveloped with a casino, shopping mall, and concert venue with the National Museum of Industrial History and the extant bank of blast furnaces reflecting the regions industrial past. Park Fundidora in Monterrey, Mexico, which preserved parts of one of the largest Latin American steel mills, also included open parkland, an amphitheater, and hotels and is connected to the city center via a man-made river way (see Fig. 3). The Tate Modern Gallery in London and the Capitoline Museum, Centrale Montemartini, in Rome, were both installed in former power plants, and the Musee d'Orsay was installed in a former Paris train station – each with much of the original fabric intact. Further, throughout North America and Europe, former industrial buildings have been converted into lofts and office buildings, and some US states have even passed legislation that allows tax credits for former mill and brownfield redevelopments (Morin, Left Coast Press 2013b). In other cases, buildings have simply been left on the landscape and have become welcome subjects for an increasing interest in industrial ruins and urban exploration (Cossons 2007: 17).

In addition to new industrial heritage developments and experiences, universities introduced

Industrial Heritage in Archaeology, Fig. 3 Aerial image of Park Fundidora, Monterrey, Mexico, developed as a large state-municipal park and recreation space with a steel museum located in and around the former blast furnace number three. Image shows the large enclosed amphitheater, partial remains of the former steel mill, and view of the city. (Bode Morin Photographer, 2010)

several new academic graduate programs in the 2000s with a broader focus on heritage management topics including adaptive reuse, museum studies, and conservation planning. The Ironbridge Institute offers graduate courses in heritage management and historic environment conservation, and the University of Leicester offers graduate degrees in museum studies interpretation, representation, and heritage. Michigan Technological University's master's program in industrial archaeology has grown to include a Ph.D. in industrial heritage and archaeology. Erasmus Mundus, a joint program with the Sorbonne (France), E'vora (Portugal), and Padua (Italy) universities, offers a master's degree in "Techniques, Heritage, and Industrial Landscapes (History, Enhancement, Education)" and a Ph.D. in applied history HTPS (History, Technology, Heritage, Sustainability). Vrije Universiteit, in Brussels, has a course in "Industrial Archaeology and Industrial Heritage," and the Conservatory of National Arts and Crafts (Paris) offers courses in the history of technology and the conservation of industrial heritage (TICCIH n.d.).

Since 1990, there has been an ever-increasing awareness of the value of industrial heritage and the importance of creating regional identities and commemorating significance. Terms like "Copper Country," "Iron Bridge Gorge," "the Ruhr," "the Anthracite Region," and "Fordlandia," all were historic references that have become brands celebrating the heritage of industrial regions. The European Union designated 2015 the year of industrial heritage, and many preserved industrial sites have become a vital part of heritage tourism. The European Route of Industrial Heritage

(ERIH), established in 1999, was developed with common branding and experiences but on an enormous scale that in 2018 included more than 1600 sites in 47 countries with 13 regional routes and 104 anchor sites (European Route of Industrial Heritage n.d.).

On an international scale, the United Nations Educational, Scientific and Cultural Organization (UNESCO) has inscribed numerous industrial sites recognized for their outstanding universal value on the World Heritage List. Part of the World Heritage Convention is to promote conservation efforts with renewed interest in significant regions and places leading to new developments, infrastructure, and tourism revenue (although in some instances, the influx of tourists to World Heritage Sites has been detrimental to conservation). TICCIH has been a strong proponent of identifying and promoting industrial sites for inclusion in the World Heritage List. Of the 832 cultural properties in 167 countries on the World Heritage List of 2018, at least 113 are identified as having industrial components or themes (UNESCO n.d.) (See Fig. 4).

The growth of heritage tourism in the United States and the expense of creating new national parks have encouraged the formation of National Heritage Areas, which with US National Park Service supports are largely local efforts to identify participating historic sites within a specific geographic area that contribute to a particular theme. The independent heritage areas, similar to ERIH, develop uniform branding, economic development systems, and heritage experiences to encourage visitors to travel to, stay in, and spend money in their region. Of the 49 US heritage areas in 2018, at least 17 had industrial themes including MotorCities (Detroit), Rivers of Steel (Pittsburgh), National Aviation (Dayton), National Coal (WV), and the Oil Region (PA) (National Heritage Areas n.d.).

The reuse role of former industrial structures is further reflected and enhanced by the greater inclusion of developers, architects, and landscape architects in international heritage conferences, showcasing not just specific conservation projects but redevelopment and tourism enhancement projects. At the 2009 TICCIH world congress in Germany, 19 of the 29 sessions of the scientific program dealt specifically with heritage issues of preservation, redevelopment, and reuse. The program included the sessions: "Creative Re-Use: Industrial Heritage, Building Assessment, Real Estate and Brownfield Redevelopment," "Industrial Heritage Tourism," "Management of Cultural and Environmental Areas," and "Large Scale Industrial Heritage Projects – Concepts and Problems" (TICCIH 2009).

Industrial Heritage in Archaeology, Fig. 4 The Big Pit, National Coal Museum part of the Blaenavon World Heritage Site, Blaenafon, Torfaen, Wales. The site offers underground tours, interpreted educational experiences, and conserved mining structures meeting the condition of outstanding universal value. (Bode Morin photographer, 2006)

Key Issues and Current Debates

The biggest issue facing the field is the continued debate over what to do with and how to manage these places. Industrial buildings and landscapes are inherently large. They can take up several city blocks or encompass multiple square miles.

Their size often makes them difficult to manage, especially when they become unused, and very costly to conserve and maintain especially in areas of declining economies. Further, their mere existence as a long-used industrial site prior to meaningful pollution regulations often means significant environmental problems. In the United States, the Comprehensive Environmental Response, Compensations, and Liability Act better known as "Superfund" was created in 1980 specifically to address abandoned hazardous landscapes resulting mostly from industrial activity. Further, many western countries have laws that mandate remediation or demolition soon after the active life of industrial places end. In the United States, for example, the 1977 Surface Mining and Control Act required that all then active coal processing plants be demolished at the end of their operations. These laws, while intended to protect human health and the environment, can create major hurdles in long-term preservation planning especially if used as a political argument in contentious debates (Morin, Tennessee 2013a).

Related to the environmental issues, large, closed, and unmaintained industrial sites are not always appreciated by all people equally, and a site's perceived value varies greatly. Some people may view industrial remains as blight in need of demolition, remediation, and redevelopment. Others see heritage value in wastepiles and the detritus of industrial activity and believe that restoration and reuse are the best courses for remembrance, identity, and economic revitalization. Others even see industrial remains as sources for unique photographic backgrounds hence the term "ruin porn." All of these reactions tend to complicate arguments for significance because not all people value the landscape the same and often some sort of consensus is needed when large remediation or conservation projects demand public support and financing (Morin, Tennessee 2013a). Further, with the growth of the academic fields of environmental and envirotech history, several studies explore the broader effects of industrial activity, namely, environmental destruction, waste generation, and the long-term effects of toxic chemicals (see Quivik 2000). Museums too started to explore issues of contamination and regeneration at former industrial sites and the broader effects of industrialization on communities (see Shrinking Cities n.d.).

The third main debate centers on the field's broad interest groups and the perceived extent of academic rigor. Perhaps more than other discipline, industrial heritage encompasses a broad array of professions including archaeologists, historians, architects, museum professionals, and engineers each with a particular interest brought to bear on industrial remains and a very active nonprofessional or avocational contingent. This eclectic mix tended toward discursive objectives as opposed to disciplines of like-trained professionals following a uniform methodological approach. This debate shows up in questions asking whether this is an archaeological field or a preservation field, whether it is a course of anthropologic study or primarily a documentation practice, and whether it is an academic field or an economic model for redevelopment. This issue within industrial archaeology, however, was addressed in the 1990s during Hudson's phase three with the demonstration that amateur groups were quite capable of providing quality work and the growth of academic programs, conferences, and journals with a clear commitment to pursuing academic questions (Cossons 2007: 13). However, the debate within conservation continues as the future of evermore complex sites is contested.

These latter evolutions of the field, however, did not eliminate or marginalize the nonprofessional. It is true that the creation of lists slowed down as the number of undocumented sites shrank effecting a similar slowdown in the traditional role for the nonprofessional. However, new roles, especially in the creation and commemoration of heritage, opened for them. Heritage interpretation and preservation had always been an important part of industrial heritage, and many of the British societies and clubs worked to not only document sites but also make them available for public tours and educational experiences; those key experiences were primarily volunteer-led museum or education-related (Linsley 1980: 43). Today, branded tourist experiences are as equally geared toward history as identity and

entertainment marketing in regional areas. This approach is augmented by the promotion of regional and World Heritage Sites, sociological studies into community memory and identity, and the need to broaden the experience of traditional museum goers and expand the industrial heritage constituency to include other members of the community who may not be as topically inclined. This newer movement increasingly includes new arts and entertainment experiences – some on a grand scale.

Future Directions

The field today seems to be focusing more clearly on its multiple roles. On the one hand, the academic side is continuing to evolve and ask serious questions of the material culture and newer studies influenced by trends in historical archaeology, for example, began to focus on Marxist approaches of class and status, gender, and resistance demonstrated in industrial site material culture (Palmer 2005). On the other hand, the heritage side can be argued to be flourishing, as far as development money is available for reuse projects, and reaching a broader more popular audience. From the UNESCO World Heritage List to recognitions of the value of industrial heritage by the European Union and the US National Trust for Historic Preservation, which included several industrial heritage sessions at its 2011 conference, the greater appreciation of industrial heritage is demonstrated among others not necessarily inclined to appreciate industrial sites and histories. But this new appeal is centered on a newer appreciation for heritage and reuse projects that have broad community benefits but do not necessarily reflect renewed interest in traditional forms of IA. While this could be a symptom of general deindustrialization, the declining need for nonprofessional documentation services, or simply a means to attract a larger audience to the field, it may be seen as diluting the broader historic and scientific focus of the field. Or maybe industrial heritage has simply fulfilled its first mission to recognize significant industrial sites, document the most important of those, and argue for a broad preservation plan and is now focusing on using those sites being preserved in new ways and settling in on more complex ways to understand the material culture and its effects on contemporary culture.

State of Knowledge and Current Debates

Roads in the Roman World

Introduction

The Roman road system, together with the sea transport network, represents one of the essential structural means, *moles necessariae* (Plin. *HN* 30.75), through which the Roman state at first established itself and then maintained its empire. In the meanwhile, the Roman civilization, thanks in part to its road system, succeeded in assimilating, merging, and transforming even the most dissimilar and distant cultural and economic influences and contributions; all of them helped the Roman civilization to take on that character of universality which enabled it to endure (Quilici 1990: 11, 22). The construction of Roman roads is governed by a strong process of abstraction which simplifies the complexity of landscape in order to get an environmental model and tool able to organize and manage space. The land is deprived of its natural features and is isolated from its context. The "milestones of nature," such as trees, rivers, hills, rocks and so on, are no longer suitable to fix a point in space, due to their continuous transformation; thus, they give way and are replaced by the well-defined milestones of the Roman state. They are stone markers set up on a roadside to indicate the distance in miles. A milestone fixes once and for all a point in space and thus it also marks time. This way, huge territories take on for the first time a definite outline; permanent military and economic landmarks and travelling times are fixed more precisely (Cat. *Orig*. 1.6; Dion. Hal. *Ant*. Rom. 2.49; Strabo 5.2.10: 20–25). The measurement of distances and the fact to have well-defined/certain points of reference on the soil is the basis of an effective planning of political, military, economic, and administrative activities. This approach of the Romans to the awareness and organization of territory arises from a complex scientific system, resulting from a mixture of geometry, engineering, geography, ethnography, and economics: this approach enables them to coherently redefine and contextualize space, by adapting it to the needs of the Roman state.

Historical Development

Rome's position at the main ford of the lower course of the river Tiber situates it near to important routes of human transhumance (Quilici 1990: 13). These overland routes linked the populations of Latium, Sabina, Etruria, and Campania along the valleys of the Tiber, Anio, Sacco, and Liri rivers. Rome became in turn an important hub, thanks to its favorable position (Cic. *de re pub*. 2.4–6; Liv. 5.54.4). Already in the fifth century BCE, the laws of the Twelve Tables regulated, in a special paragraph, the road size (Paul., Fest., 508.22). The Roman road system passed in a short time from a series of roads radiating from its center to the near cities, which were called with the name of the city to where they led (*ViaOstiensis* leading to Ostia, *Via Ardeatina* leading to Ardea, *Via Tiburtina* leading to *Tibur*, *Via Collatina* leading to *Collatia*, and so on), to a long-distance and really extended road network. At the end of the fourth century BCE, that was going to become a long-distance and remarkably

I

vast route. The construction of roads started at the end of the fourth century and continued for all the third century BCE following step by step the territorial expansion of the Roman state and, above all, the creation of strategic bases such as the *coloniae maritimae*. These settlements needed to be linked to Rome to answer in full the military, economic, and trade requirements of both colonies (*coloniae*) and allied cities (*socii*). *Tarracina Anxur*, founded in 329 BCE, was connected to Rome by the *Via Appia* in 312 BCE, while *Cosa*, a colony of 273 BCE, was connected to Rome by means of the *Via Aurelia*. From the third century BCE, the *Appia*, *Latina*, *Tiburtina* and *Valeria*, *Salaria*, *Flaminia*, *Aemilia*, *Postumia*, *Aurelia*, *Cassia*, and *Clodia* roads, along with the two roads called *Popilia*, played primary roles in the unification of the Italian peninsula. In particular, the most important roads in military, colonial, and economic terms were the great roads leading to the Etruscan territories between the third and the second centuries BCE (the *Via Aurelia* coast road, the *Via Amerina*, *Via Clodia*, and *Via Cassia*) and the pathways built towards northern Italy: the *Via Flaminia*, probably built by Gaius Flaminius during his censorship in 220 or 219 BCE, that was the axis for the colonization of the *Ager Gallicus* and for the conquest of *Gallia Cisalpina* that led to *Ariminum*; the *Via Aemilia*, built by the consul *Marcus Aemilius Lepidus* in 187 BCE, linking *Ariminum* to *Placentia*, on which the land divisions of the fertile territories of the Po valley were based; and the *Via Postumia*, which established the boundary line between the Roman world and the subalpine regions around the second half of the second century BCE, when it was built by Spurius Postumius Albinus. This road connected *Genoa* to the Ligurian sea and *Aquileia* at the northern end of the Adriatic. Finally, the *Via Popilia* road, built in 132 BCE between *Ariminum* and *Padua* by P. Popilius and finished by T. Annius, led to the southern end of peninsula (Quilici 1990: 17). From a building viewpoint, the first roads were a mere adjustment and integration of previous routes, and they did not possess the permanence that would be the distinguishing feature of the Roman roads for centuries, that is, the paving with *lapidibus perpetuis*, according to the well-known definition of the *lex Iulia municipalis* of the first century BCE (*CIL* I, 206). The presence of such paving demonstrates the existence of a codified building technique that complied with standard procedures. As the building techniques developed, roads become "living beings" (Quilici 1990: 11) and soon began to be surrounded not only by spontaneous settlements but also by elements at the basis of civil life and organizing territories such as *castella*, *conciliabula*, *fora*, and *vici* (Becker 2002; Gros and Torelli 2007). Roads, in the Roman world, created a community. Towards the end of the Republic, the road system connected Rome to all the main cities of the peninsula. Two important routes, the *Via Domitia* and the *Via Egnatia* (Fasolo 2005), led to the farthest western territories of the Roman Mediterranean. In the imperial period, the road system became widespread also across the provinces as it was across Italy, with an overall extension of more than 120,000 km.

Law System

In the Republican age, the skills about the construction of public roads, *viae publicae* and *militares*, fell within the competence of the Senate (Pekàry 1968: 75), which allocated funds from the public treasury (*aerarium*) necessary for the upkeep of the infrastructure. Later, funds coming from public revenues were used (S.H.A. *Pertinax*, 9; Suet. *Aug*. 30.3; *CIL* V 8102, 8103, 8106). Evidence coming from milestones as well as from the historical and literary sources suggests that the magistrate in charge generally was a consul or a *praetor* and later a proconsul, that is, a magistrate having *imperium* who, as Ulpian points out, had the *ius publicandi*, that is, the power to dispossess people of lands and properties for public needs (Pekàry 1968: 49; Radke 1971: 41; Suet. *Vesp*. 5; Plin. *HN* 18.11; Ulp. *Dig*. 43.8.2.22; *Thes. Ling. Lat*. 4.571). Of course, the construction of roads could be also authorized by a law, such as *Lex Sempronia viaria*, issued by the tribune Caius Gracchus (Plut. *CG* 7; App. *Bell. Civ*., 1.23). Romans classified roads according to the juridical or administrative use they made of the same: *privatae*, that is, built by private citizens on their own lands (Ulp. *Dig*. 43.8.2.21–23);

publicae, if all the people were allowed to pass through (*publice ire*), to transport goods (*publice commeare*), and if it had been constructed on public soil by a public authority (*publice munire*) (Fest. 508.20; Sic. Flac. *De Cond. Agr. Gromat*. 1.146.2; Ulp. *Dig*. 43. 8.2.21; Isid. *Or*. 15.16.5); *militares*, that is, very strategic roads that crossed regions, not only public but also of great public interest, having special features (Rebuffat 1987: 52–67); and *vicinales*, connecting rural villages (*vici*) among them and to the main routes, as they depended, from an administrative viewpoint, on the local authorities. Similar to the latter were also the *Viae agrariae* (Ulp. *Dig*. 43.8.2.22), the *Viae rusticae* (Ulp. *Dig*. 43.8.2.22), and the *Viae paganicae* (Chevallier 1997: 33). Traffic on the aforementioned roads was free. Quite strict rules were imposed to safeguard the integrity and the use of such infrastructure. It was forbidden to occupy a road, to widen or to narrow it, to modify its level, to pave it or vice versa to remove the existing pavement (Ulp. *Dig*. 43.11.1–2), to unload earth (Ulp. *Dig*. 43.7.2; 8.10.2) or litter it, or anyway to damage it (Ulp. *Dig*. 43.8.2.35). Some traders, such as blacksmiths, were permitted to show and advertise their handicrafts, such as wheels, along them or, in the event of *fullones*, to spread out linen along the route, provided that this did not hinder circulation (Ulp. *Dig*. 43.10.4).

Construction

The ancient epigraphic, historical, and literary sources, though providing a quite wide range of phrases to indicate the construction of a road such as *viam innovare*, *instituere*, *munire* (Cat. *Agri*. 2.4), *sternere*, and *struere*, generally give a few indications without providing a detailed description of the road building technique. Only the first-century CE poet Statius (*Silv*, 4.3.40 ff) gives a description of the coast road between the mouth of the river *Volturnus* and *Puteoli*, the *Via Domitiana*. Other details may be inferred by analogy from some selections of Vitruvius (*Arch*. 7.1) and Pliny the Elder (*HN* 36.186), devoted to building paving systems. Most of the information used to reconstruct the Roman road technique comes from the archaeological research carried out on surviving routes (in particular from the documentation of some portions of the *Viae* Salaria, Appia, Flaminia, Aemilia, and Postumia). We have to assume that the road builders studied the soil, paying special attention to the stability of foundations. One of the aspects taken into due consideration by road builders was the one linked to the protection of roads from superficial water seepage, which could cause instability. Roads were designed, and the road construction sites were superintended, by civil or military architects and engineers, often called back to service, *evocati* (Vitr. *Arch*. 1.praef.2); *Firmitas*, *utilitas*, and *venustas* (solid, useful, able to endure the passing of time, beauty, graceful) were the three inspiring principles of their school. The implementation of works, performed according to circumstances, with or without the contribution of the cities involved in the route, was committed to troops, thus rescued from idleness (Liv. 39.2.3); to subject populations (Tac. *Ann*. 1.20.1; Cic., *Pro Plancio* 8.17); or to manpower found by private contractors. Works were supervised by *quaestores* (treasurers) and *praefecti fabrum* (supervisors of craftsmen). The task of defining the route was committed in particular to land surveyors, who used precision instruments and procedures known also in other fields (Blume et al. 1848–1852). The final route was fixed on the ground by means of further alignment of points along which two parallel trenches were carved. The Romans generally tried to reach their various destinations by the most direct and inexpensive means, by avoiding to modify the soil's morphology but also avoiding dangerous sites which could jeopardize the same route (i.e., valley bottoms that were subject to flooding). Due to this, the Romans had sometimes to remarkably extend the routes (Quilici 1990: 20–3). The allowed radiuses of curvature were small, probably because of the structural features of chariots. Yet, soil sometimes imposed special solutions as well as the unavoidable implementation of special engineering works. Some of them, for example, many bridges, still arise admiration and are perfectly working still today (Galliazzo 1994–1995). The most frequent cases were linked to the crossing of marshy areas and to the overcoming of natural gradients

and obstacles: bridges, some of which remain in use, in the most suitable passageways; road embankments; viaducts; or, where it was not possible to build them, wooden structures, road substructions downhill, retaining walls uphill, soil removals, performance of cuttings in the rock, or drilling of galleries (Quilici 1990: 22). As regards the real route, the reconstructed building sequence contemplated, as a first step (*primus labor*), the delimitation of the route's edges by means of two parallel furrows in the soil (*inchoare sulcos et rescindere limites*). A ditch was excavated inside them that reached a basis solid enough to bear the weight of the road surface (*alto egestu penitus cavare terras*). With a procedure very similar to the one described by Vitruvius for the casting of concrete, the ditch or *gremium* was then filled up, *mox haustas alter replere fossas*, with layers of material, usually four in number; yet, their number, shape, contents, and thickness were affected and determined by the specific soil conditions as well as by the available building materials. The entire filling procedure of the ditch, whose overall depth could even exceed 1.5 m, should ensure uniformity to the road surface, by preventing the creation of chasms and collapses (*ne nutent sola*, *ne maligna sedes/et pressis dubium cubile saxis*). The foundations consisted of a layer of at least 30 cm thick, similar to *statumen*, that was made up of medium- to large-sized stones aimed at consolidating the natural soil. Over it, the *rudus*, that is, a mass of cobblestones, bound with clay, (seldom with mortar) was cast, hammered with maces in order to be made firmer, and arranged on horizontal layers. This layer of finer material, which was aimed at drainage, was covered in turn by the *nucleus*, made up of ballast with large gravel smoothed by means of pile drivers (*fistucatio*) and rollers (*ingenti aequanda cylindro*), and whose ridge was slightly bent in order to accompany the laying of the *summum dorsum*, *crusta*, or *pavimentum*. This way, the rainwater flowed in the bumps alongside the road, immediately after the pavement or *crepidines* that sometimes came alongside it. The *pavimentum* could be made up of mere dirt (and in that case it was called *Via terrena*), of gravel or crushed stones (and in that case roads were called *Viae glarea stratae* or *glareatae*), of polygonal and uneven slabs of basalt, or, if available, of limestone, smoothed in the upper part and wedge-shaped in the lower part, accurately laid (*Viae silice* or *lapidibus stratae*). The paving procedure was called, for sake of precision, *silice sternere; lapide, saxo quadrato sternere*. Statius celebrates with pride the *ingenti plaga marmorata dorso*. Sometimes, especially on steep routes, some parallel ruts were excavated in the pavement to lead the wheels of vehicles, by preventing thus their going off the road, in particular in case of ice. The width of the *Via publica*, unlike the private one (whose minimum width was established by law), depended *quantum ratio utilitatis permittit* upon the various conditions and needs, just like the pavements which sometimes came alongside it. Width was extended in the busiest areas and at all events it was such as to allow the transit of vehicles. The construction was followed by the laying of stones which delimited the route and of milestones and mounting blocks which made getting on and off a horse easier.

Milestones

Distances along the route were indicated by large boundary stones up to 3 m high and with a diameter of 60–80 cm, driven into the ground beside the road at the distance of a Roman mile from each other (1478.5 m) and therefore called "milestones." The earliest known milestones date between the third and second century BCE (*ILLRP* 1277; *CIL* I^2 21; *CIL* I^2 22, 617, 618, 619, 620) and have a cylindrical shape. Generally speaking, a milestone carries the name of the person who laid it down and this name may not coincide with the road builder or restorer, as well as his office and the distance from the beginning of the road or from a nearby center and, in case, the reason why that road had been constructed or restored. According to Strabo (5.3.8), the habit of signalling with regularity the distance covered or still to be covered was a Roman innovation, introduced or at least made official and mandatory in the second half of the second century BCE by means of the *Lex Sempronia viaria* of Caius Gracchus (Plut. *C. Gracc*. 7).

Management

It was only a strong organization system that allowed the Roman road network to remain in use for such a long time. In the Republican period, after the conclusion of the construction works, the *aediles* living within ten miles of Rome were in charge of the management of roads (*Lex Iulia municipalis*, FIRA, I, n. 12. *CIL* I^2, 21, 22, 829). In any event, such tasks, together with other administrative functions, were also within the discretion of the ordinary magistrates having *aedilicia potestas*. The extension of the road system soon implied the creation of some officers specifically devoted to the care of roads, called *curatores viarum*, who appear in the sources from the first century BCE. At the end of Republic, the activity of such *curatores* went along with the evergetism of some renowned public personalities. Marcus Agrippa restored the entire Roman road system at his own expense and Augustus restored the *Via Flaminia* in 27 BCE. The creation of the duty of *cura viarum* is attributed to Augustus in 20 BCE; this fell under the direct purview of the *princeps* (Suet. *Aug*. 37). He gave directions to a *collegium* of *curatores*, whose number was unknown. They were selected at first from among the *praetores* (*CIL* I^2, 200, 744, 751, 808, Plut. *Caes*. 7; Cic *ad Att* 1.1.12; Appian. *Bellum Civile* 2.27). Later, the *curatores viarum* reported to the praetorian prefect. As they were fully responsible for the complex management of the road system, their duties included the control, maintenance, and restoration of roads and annexed works; property protection; and the enforcement of the police regulations. Their office also included financial duties. With regard to scope, it could range from one or more roads to the whole road system. The mandate of *curatores* was more prolonged and more variable in time when compared to that of the other magistrates; it could be extended up to 11 years, and it was clearly influenced by specific needs in order to ensure a proper exercise of their functions. In the provinces, the *cura viarum* was entrusted to governors. Starting from the second century CE, the *cura viarum* changed from *honores* into *munera*, thus becoming a basic stage of the *cursus honorum*.

The *Cursus Publicus*

The relationship between the central government and the provinces of the Empire was kept by means of a state service that ensured the land and sea (*CIL* 14.2045; Sen. *Ep*. 67) transmission of all information and of the land mail, the *cursus celer* or *velox* (Amm. 21.9.4), as well as the transport of people and goods *ex causis necessariis* (of public interest), the *cursus tardus* or *clabularis* (*Cod. Theod*. 8.5.62). The service took place thanks to an organization widespread all over the Empire, hinging on *mutationes*, *mansiones*, *praetoria*, and *palatia* able to provide full assistance along all the routes (Cuntz 1929: 130; Seek 1846–1851; Holmberg 1933; Pflaum 1940: 189–390; Pekáry 1968; Quilici 1990: 92; Uggeri 1995: 140–144). Scholars agree upon the origin of the wide administrative plan conceived and started by Caesar and implemented by Augustus already in the first years of his kingdom. Caesar mentioned a system he himself devised, with horse soldiers, *dispositi equites* (Caes. *bell. Civ.*, 3101; Liv. 27.43), who, placed at a certain distance from each other, had the task of quickly conveying the news of his victories; yet, a similar structure probably already existed long before. Under Augustus, such horse couriers became more numerous; they were called *iuvenes* and their most difficult task, in addition to the mere delivery of correspondence, was that of informing the emperor of the events occurring in the provinces. The main roads were equipped with *stationes*, which is to say places to stop and change horses and draught animals; the local populace supported the cost of these *stationes*.

The main sources to reconstruct the structure of the cursus publicus (corsive) in the Augustan period are a passage from Suetonius (*Aug*. 49.3), the edict of Sextus Sotidius Strabo Libuscidianus, quoted in an inscription found in Burdur (*S.E.G.* 26, 1979, n. 1392) and a reference to such measure that can be found in a passage from Procopius (*Arc*., 30, 2). In the light of the above-mentioned documents, the Augustan institution seems to be the first of all not only a mail service but rather a true information service and a transmission of directions by means of couriers, *ut adnuntiari cognoscique posset* (Suet. *Aug*. 49.3), that was

essential for the security of State. According to the edict of Sextus Sotidius, the main users of such a service were travellers for reasons of State provided with a special permit referred to as *diploma* (Tac. *Hist*. 2.54; Plin. *Epist*. 10.45, 46, 64, 120, 121), a written authorization bearing the imperial seal (Suet. *Aug*. 50). To such travellers, listed in the edict according to a hierarchical order, cities and villages had to supply up to ten chariots and as many mules (a number that could be doubled in case of donkeys). Users had to pay for the services supplied for a precise distance (that in the edict at all events did not exceed 40 *stadia*). No one could benefit from free-of-charge vehicles. Private citizens, especially if they were merchants transporting goods for private purposes, could not be supplied by these means. The members of the *comitatus*, those who supplied their services in the provinces, together with the *liberti*, the Emperor's servants and animals, could benefit from the free accommodation in the *mansio*. In the Imperial period, the granting of permits to use the service, called *evectiones*, was progressively extended to soldiers as well as to the wives and sons of the people having the right, thus becoming a privilege difficult to be both granted and controlled. As a consequence of this, there was also an increase in the number of abuses and outrages to the detriment of local communities, which had heavy duties and obligations for the management of the service. Thus, emperors such as Trajan, under whom the definition of such service as *cursus publicus* appeared for the first time, had to intervene in order to curb such abuses. Also the future emperor Pertinax (SHA *Pert*. 1.6) was forced to continue his journey on foot, as he was found unprovided with any permit. Under Nerva the operational costs became the charge of the imperial tax office. Under Hadrian, the *cursus publicus* became widespread throughout the Empire. In the Constantinian period, the *clerici* of the *ecclesia catholica* began to use the *cursus publicus* both on the occasion of events such as councils, synods, and consecrations and when they had to take part in the most various official celebrations, within the framework of a progressive increase in privileges and exemptions. Also in this case, the achievement of *evectiones* and *tractoriae*, which is to say food during journeys, degenerated into abuses. The *clerici*, Ammianus Marcellinus remarks (Amm. 21.16.18), crowded the roads on the pretext that they had to attend to councils at the expenses of State from one hand to another of the Empire. We do not know in detail the structure and regulations of such service. At first, the management was undertaken by Augustus, who entrusted two *praefecti* of *praetorium* also with the task of supervising and controlling the *liberti*. With Hadrian, the figure of the *praefectus vehiculorum* was introduced, who had the task to supervise the overall progress of the service and the conditions of roads and of *stationes*. Within this organizational structure, the post houses, *mutationes*, and *mansiones* were essential for the efficiency of service. They were subdivided into premises for accommodations, stables, and warehouses; there were also very often bathing facilities. In the late Republican period and during the principate, their management was committed to the contractors who won the public bidding. Contractors, which in the first three centuries of the Empire managed the *stationes*, were replaced in the Constantinian period by the *mancepes* or *praepositi mansionum*. The praepositus was generally a curial and a member of a city council that was equivalent to the Roman Senate, having religious, administrative, and financial duties, particularly wealthy and, for this reason, obliged to comply with his obligations towards the city and the State. Among the main duties of the *praepositus* were the procurement of animals, their custody and care, their recovery in the case of theft, the obligation to assign them to authorized travellers, and the control that no more than five of them (i.e., the eighth part of the equipment of each *statio*) could go out from the *mansio* daily. Letters kept in leather bags were delivered by the *tabellarii* (Cic. *Phil*. 2.31; *Att*. 12.1; Plin. *Ep*. 10.64), assisted by *cursores*, *speculatores*, *veredarii*, and couriers who carried the most urgent messages on horseback. Similar tasks were carried out in this field of the imperial administration by the *frumentarii* and, with Constantine, by the *agents* (*Cod. Theod*. 6.27.1–3), who transmitted the imperial autographs, and the *principes agentium*, who performed supervision

and control. Under Constantine, the compliance with regulations was verified by *curiosi* (inspectors). For the performance of their tasks, the *mancipes*, the *curiales*, or even the *praepositi mansionis* availed themselves of *stationarii*. The care of draught animals was remitted to the *stratores* and to the *muliones*. The *hippocomi* had the task of accompanying travellers from a *statio* to another and of taking vehicles back. In addition to them, there were the chariot drivers or *carpentarii*; the people in charge of the care and transport of luggage, the *bastagarii*; and for the most burdensome tasks, the *catabolenses*. Special escorts protected travellers from *latrones* and *grassatores* who swarmed in the roads. There were essentially two kinds of journeys permitted by the service: the *cursus celer* or *velox*, for which light coaches (*redae*) were used, and the *cursus tardus*, for which heavy coaches were used, suitable for the freight of goods. Private citizens, on the contrary, used their own couriers (*tabellarii* and *cursores*) or they resorted to the trade flows to forward goods and correspondence.

Speed

The sources reveal some hints on travelling times in the ancient world that, at all events, were not always the same, due to a series of variables. While a traveller on foot generally covered a distance of 20–25 miles (30–35 km) *per diem*, the horse couriers of the *cursus publicus* usually managed to average 5 miles per hour, totalling 50 miles per day (75 km). We learn from Ovid (*Trist*. 4.5.1–8) that it took 9 days for a letter to go from Brundisium to Rome, which were 365 miles distant, one from the other. We also learn that it took 9 days for a letter to reach Trajan from Bithynia in Asia Minor. According to Plutarch (*Cato Maior* 14.4), Cato was certainly faster if compared to such averages, since in 191 BCE, he covered the distance between Brundisium and Rome in 5 days, by averaging 80 miles a day (about 120 km). Caesar was even faster, as in 58 BCE he reached Geneva (800 miles from Rome) in 8 days (Plut. *Caesar* 14.4), just like Tiberius, who rushed in 24 h from Pavia to Thuringia, a distance of 200 miles, in order to see his dying brother, Drusus. Journeys with chariots were obviously longer (Plin. *HN* 7.84; *Val. Max*. 5.5.2). The *carruca* averaged 5 miles per hour. It took 7 days for Cicero (*Att*. 5.4–6) in 51 BCE to cover the distance of *Via Appia* from Beneventum to Tarentum, presumably by chariot. Until the route reached Venosa, the mountain route forced him to average 19 miles a day, whereas in the plain he managed to average 32 miles *per diem*. Horace, instead, covered the distance between Rome and Brundisium, by passing through the future *Via Appia Traiana*, in 15 days. Cicero (*Pro Rosc*. 7.19) covered 56 miles (83 km) separating Rome from Amelia along the *Via Cassia* and *Via Amerina* in a 10-h night journey using a light chariot.

Aqueducts

Aqueducts, constructed on high arcades (*arcuationes*) which still today cross the Roman countryside, are among the most impressive and original creations of Roman architecture and civil engineering. The Romans inherited the technical achievements about water conveyance techniques that were very popular in the Mediterranean area and in the Near East (the aqueduct of Jeruan Ninive, the hydraulic works of Jerusalem in 700 BCE, the tunnel of Eupalinos of Megara in Samos in 530 BCE, the Hellenistic works of Patara and Pergamon). Above all, as many classical authors remind, the Romans were the followers of the great Etruscan engineering. In fact, the Etruscans implemented the first hydraulic works in Rome (the reclamation of the Roman Forum, the construction of the Cloaca Maxima under Tarquinius Priscus and Tarquinius Superbus), besides the huge reclamation and canalization works implemented in their own country and in the Po valley. Varro maintains that water divining, originated in Etruria (Varro *Men*. Frag. 444); the Romans created an awareness of water as a public asset. The first urban water distribution network they created was made up of architectural works, urban spaces, and works of art. This network was able to ensure citizens a *per capita* quantity of water that was the double of the quantity available to a modern Roman citizen. In the territories of the Roman Empire, aqueducts numbered about 200 (at Antioch on the Orontes,

Merìda, Ephesus, Berenice, Tarraco, Segovia, Carthage). Such monuments are kept until nowadays and sometimes used to feed some fountains of the modern Rome. A series of historical, literary, and technical written sources (Frontinus, Pliny, Vitruvius, Procopius) are the basis of our reconstruction of the building techniques used by Romans.

The first step for the creation of an aqueduct was the search for and the determination of a rich spring. The methods used were the examination of the soil geomorphology and of vegetation (Vitr. 8.1). After detecting the presence of water, the latter was then subjected to an organoleptic test so that its salubrity as well as its limpidity of the water could be assessed, by taking the health of the inhabitants living very close to the spring into consideration. Nevertheless, Frontinus remembers, the discovery of the spring of *Aqua Virgo* occurred casualty. A young girl – hence the name *Aqua Virgo* – is said to have indicated certain water veins to some soldiers, involved in looking for springs. When they followed these up and dug, they found an enormous quantity of water. The event was recorded by a painting in a small shrine set up near the source (Frontin 1.10).

The water collection procedures varied. In some cases (*Anio Novus*, *Marcia*), springs were collected in a masonry tank coated with a waterproof layer of *opus signinum*. They flowed then into a *piscina limaria* (settling tank) from which the canal (*specus*) branched off.

The conveyance of water to its users, sometimes over great distances, was performed by means of an open conduit system, which is to say, by exploiting the force of gravity. Water flowed thanks to the force of gravity in a canal to which the Roman engineers ensured a suitable slope (*declivitas*) preventing water from reaching a speed that could jeopardize the stability of that structure, in the presence of a constant slope. Thanks to this criterion, the height of the aqueduct progressively decreased from the spring along its route, by forcing the route to meander.

It was essential to maintain slopes *mensura declivitatis*, that is, the optimal required slope, so that the topographic drop may enable water to flow without excessive or poor speed between the spring and the place where water was used (Vitr. VIII, 6,1). This was attained thanks to some topographic tools such as *chorobates*, but also the *dioptra* and the *libra acquaria*, as well as the use of arches. The oscillation of slopes of the Roman aqueducts is remarkable and sometimes diverges very much from the theoretical directions of Vitruvius who suggested slopes not lower than 5%, of Pliny, and Frontinus, respectively.

The water flow was funneled to a masonry canal, called the *specus*. When it was underground, especially far from cities, or in other tunnels, such a canal had some vertical wells, *lumina*, at regular intervals, which linked it to the surface.

The walls of the canal were built either with stone (i.e., tufo). The conduit covering could be, in the same aqueduct, sometimes flat and some other times a sloping roof or an ogival arch. The width of the canal section was proportional to the flow and at all events it sometimes varied for no apparent reason.

Some settling tanks were arranged at regular intervals along the route, where there were often the massive structures of *dividicula* or *castella* which enabled the collection of water.

When the aqueduct had to cross rivers or valleys, and at all events to ensure the required slope, the engineers resorted to the typical structures of Roman architecture, that is, the arch with a series of arcades, often multilevel. In the Segovia aqueduct, the arches reached 50 m in height, whereas in the *Anio Novus* in Rome, they reached 32.3 m in height, for 9.593 km of length. The material most commonly used was *peperino* and only centuries later it was reinforced with some restoration works in concrete and masonry.

The Aqueducts in Rome

Aqua Appia (312 BCE)

The most ancient aqueduct of Rome carried water from the springs of the *Prenestini* mountains; prior to its construction, the city had relied upon wells and the water of Tiber river. The aqueduct covers a route of about 16 km, most of it

subterranean, and could carry an estimated 73,000 m^3 of water per day.

Anio Vetus (272 BCE)

The *Anio Vetus* followed a course of about 64 km from the Anio river to Rome and carried 176,000 m^3 of water per day.

Aqua Marcia (144 BCE)

The *Aqua Marcia* stretched from the springs of the Anio valley to the Capitoline Hill, covering a route of about 91 km and carrying 187,000 m^3 of water per day.

Aqua Tepula (125 BCE)

The *Tepula* carried 18,000 m^3 of water per day from its springs to Rome; the water is warm at its source in the Alban Hills, thus explaining its name.

Aqua Julia (33 BCE)

It came from the territory of Tusculum, with a route of 22 km, and it provided Rome with about 48,000 m^3 of water per day.

Aqua Virgo (19 BCE)

It provided 100,000 m^3 of water per day after a route of about 20 km from the Alban Hills. It was restored in 1453 CE and today still feeds the Trevi Fountain in Rome.

Aqua Alsietina (2 BCE)

It was probably built to feed the *Naumachia* shows, which took place in Trastevere. Its length was about 33 km and its flow 16,000 m^3, carrying non-potable water.

Aqua Claudia (38–52 CE)

It is the most impressive aqueduct as it stretches for 16 km on 64 big arches. It carried 184,000 m^3 of water per day from the valley. It fed the lake of the emperor Nero's *Domus Aurea*.

Anio Novus (38–52 CE)

With its route of 86 km from the Anio valley, partly shared with that of the *Aqua Claudia*, it provided Rome with 190,000 m^3 of water per day.

Aqua Traiana (109 CE)

The aqueduct that fed the Baths of Trajan collected the water coming from springs of the area of Lake Bracciano after a route of about 32 km.

Aqua Alexandrina (226 CE)

The last of Rome's aqueducts, it fed the Severan public baths (*thermae*) with a super-elevated route, coming from the springs of Pantano Borghese.

Inner Ionian Sea Archipelago: Archaeological Survey

Nena Galanidou
Department of History and Archaeology, University of Crete, Rethymno, Greece

Introduction

Meganisi and its satellite islands lie in the Inner Ionian Sea Archipelago, a relatively short distance from Aetoloakarnania and Lefkas (Fig. 1). The abundance of top-quality flint and the presence of small wetlands and karstic cavities were the first points that attracted our attention to this corner of western Greece. But there was something more. In the Pleistocene, the short distance between these islands and the neighboring Lefkas and Aetoloakarnanian coast, combined with the shallow seabed in this area, meant that changes in sea level during glacial and interglacial periods would have caused the islands to become alternately connected to and isolated from the larger landmasses. Thus, over time, new living conditions and environments were constantly created for the Paleolithic communities of southeast Europe, which responded to these in their turn. The islands of the archipelago form fragments, the higher tips, of the original Pleistocene landscape, a large part of which now lies submerged under the sea. It was only after the first millennia of the Holocene that the coastline assumed its present form and offered to the communities of late prehistoric and historical times a new set of insular attractions (Fig. 2). Marine and fresh water resources have been bountiful, and it is no coincidence that the coastline of our research area is today protected by Natura 2000. From a diachronic perspective, then, Meganisi and its neighbors posed a methodological challenge for the realization of a hybrid island archaeology – alternating as it was between mainland and islands, passing points, and landing places – on a small and viable spatial scale.

Key Issues

The project was a University of Crete initiative undertaken in collaboration with the Greek Ministry of Culture. It had two main objectives: (1) the study of the archipelago's prehistoric and historical trajectories and links to the trajectories of the larger landmasses to the east and west (*regional* scale) and (2) the identification of prehistoric sites that could be further tested by excavation in the future (*site* scale). The *project design* comprised *archaeological survey* to shed light on human activity through time and space as well as *archival*

Inner Ionian Sea Archipelago: Archaeological Survey, Fig. 1 Map showing the area of study, the Inner Ionian Sea Archipelago in west Greece, delimited by the mainland Greece (Aetoloakarnania), Lefkas, and the northern tips of Kefallinia and Ithaki

and anthropological research to reconstruct natural and cultural landscape history. It was guided by interdisciplinary collaboration of archaeologists working with specialists in geology, geography, oceanography, biology, social anthropology, and architecture.

The *archaeological survey* was conducted in Meganisi, Thilia, Kythros, Petalou, Nisopoula, Formikoula, Atokos, and Arkoudi in two field seasons in summers 2010 and 2011. A geographical information system (designed in ArcGIS 9.3) provided the platform for the work in the lab and the field. At the outset, multiple layers of *cartographic information*, in the form of topographic maps (1:5,000), historical maps (Fig. 3), geological maps, and satellite images,

were compiled, superimposed, and consulted. As surface inspection progressed, data on finds, sites, and monuments was also gradually integrated. The larger islands were divided into 100 × 60 m transects with a numeric designation (Fig. 4a); the smaller islets were explored as individual transects. Information on place names, landscape features (e.g., a doline, a cave), and structures (e.g., a threshing floor), collected by local informants or through surface

Inner Ionian Sea Archipelago: Archaeological Survey, Fig. 4 *Top*: the Kythros grid. *Bottom*: map showing the coverage at Kythros (*green*) and the areas with no access (*brown*)

Inner Ionian Sea Archipelago: Archaeological Survey, Fig. 5 The steep relief at southwest Meganisi. *Arrows* showing a coastal cave with submerged floor and a multiperiod site on *top* of a limestone cliff near the recently opened road

exploration, was mapped on transects and guided the priorities of research.

Surface exploration proceeded in *transects* by teams of 5 fieldwalkers spaced at 12-m intervals. Team members walked in parallel lines, each scanning the ground to right and left (Fig. 4a). They collected and bagged all artifacts seen on the surface and recorded visible structures or architectural remains. Each team worked with a coordinator, an experienced archaeologist responsible for positioning his/her team in the field with the aid of a portable GPS, compass, satellite, and topographic maps of the day's plan of coverage. Upon completion of a few transects, the teams stopped for evaluation. At this point coordinators wrote in the day book, made plans of any notable structures, and sorted finds. Leaving behind the natural flint debris was necessary since students were often unable to distinguish those from artifacts in the course of ground scanning. Under a tree or in the open air, these stops for inspection, find sorting, and evaluation were opportunities to teach students the archaeology fundamentals and the nature of the materials.

Sites were designated on the basis of three criteria set up by the pioneering work by Cherry et al. (1991) at Keos Island: high artifact *density*, *continuity* in artifact distribution over a contiguous area, and *discreteness*, that is, the area has a distinct edge, beyond which artifact density falls of markedly. Site coordinates were recorded with a portable GPS and transferred to the GIS database.

The original plan was to cover one third of the archipelago's 30 km^2. In practice, a little less than 7 km^2 was examined. Vegetation, steep relief, and seabird habitats proved to be the major obstacles to meeting our original coverage plan (Figs. 4b and 5). Although team coordinators were prepared for the topographic and accessibility conditions of the next day's assigned units of work, more often than not the satellite images (even those only a few years old) were depicting a landscape that had changed dramatically due to either vegetation overgrowth (western Greece receives more rain than any other part of the country) or intense construction activity and road opening especially along the coastal areas of Meganisi. In the smaller islands covered by thick and thorny vegetation, fieldwalking could only take place along paths created by grazing animals or water erosion.

Future Directions

However the results were positive. The survey recovered 20,000 artifacts and 30 sites dating from the Paleolithic to the twentieth century, with a hiatus between Late Antiquity and the eighteenth century. The finds bridge the gap

between the archaeological record of the Ionian Sea and that of mainland Greece (e.g., Bailey et al. 1997; Forsén and Tikkala 2011; Wiseman and Zachos 2003). More importantly they lend themselves to discussing and interpreting the island record in terms of cultural and natural events that are distinctive to the coastal areas of Western Greece. Working on very small islands in a geologically active part of the world, we have been aware that archaeological site preservation and visibility is largely dependent upon eustatism, tectonic movements (including coastal uplift or subsidence and local sea-level rates of change) and high-energy events (including wave action and tsunamis). Thus although the Inner Ionian Sea Archipelago survey begun on land, we have developed a special interest in the sea and in the information still locked up on the drowned prehistoric landscapes of the Ionian shelf.

Institute for Archaeologists (IfA)

Kate Geary
Institute for Archaeologists, Reading, UK

Basic Information

Institute for Archaeologists
SHES, University of Reading
Whiteknights
PO Box 227
Reading RG6 6AB
United Kingdom
http://www.archaeologists.net

Mission Statement: "We advance the practice of archaeology and allied disciplines by promoting professional standards and ethics for conserving, managing, understanding, and promoting enjoyment of heritage."

The Institute of Field Archaeologists (IFA) was founded in 1982 in order to facilitate self-regulation within archaeology and related disciplines through the setting of ethical and quality standards in archaeology, http://www.archaeologists.net. Over the last 27 years, the Institute's *Code of Conduct*, *Standards and Guidance* and Registered Organizations scheme have become the benchmarks of professional practice in archaeology in the United Kingdom. In 2009, IfA changed its name to the Institute for Archaeologists to better reflect its range of membership, which includes curators, contractors, consultants, and academics working in all areas of the historic environment. The Institute is governed by an elected Council, supported by a range of voluntary committees, area and special interest groups, and a small number of dedicated staff.

The Institute for Archaeologists provides a range of services for its members, and most importantly a voice for the sector. It represents around 3,000 individuals and 70 Registered Organizations that have shown their commitment to meeting IfA standards. Individual membership is awarded at five grades: Student, Affiliate, Practitioner, Associate, and Member. The last three are corporate grades and membership is assessed by a committee of peers on the basis of a portfolio of evidence demonstrating technical and ethical competence. Members agree to be bound by the *Code of Conduct* and by-laws of the Institute and a disciplinary procedure is in place to deal with allegations that the *Code* has been breached. A compulsory Continuous Professional Development scheme allows for ongoing assessment of members' skills and competence and ensures that these are kept up to date.

The IfA also operates a quality assurance scheme for organizations – the Registered Organization scheme. Those organizations who are registered with the IfA (identifiable by their use of the IfA kitemark) have formally resolved to carry out their work in line with the IfA *Code of Conduct* and other by-laws. The work is controlled by a full Member (MIfA) of the IfA, their status as a Registered Organization is reviewed regularly by the Institute, and any complaints are investigated and appropriate action taken. Anyone wishing to secure the services of an archaeologist is strongly recommended to contact a Registered Organization.

Major Impact

The Institute for Archaeologists exists to advance the practice of archaeology and allied disciplines by promoting professional standards and ethics for conserving, managing, understanding, and promoting enjoyment of heritage.

As well as accrediting individuals and organizations, the IfA continues to develop and promote standards and good practice guidance and has a vital role in promoting the interests of archaeology and archaeologists to government, policy makers, and industry. In particular, IfA works closely with other sector bodies to lobby government on key areas of legislative and policy change. The IfA publicizes the work that it does through its in-house magazine *The Archaeologist* and Yearbook, through a range of professional practice papers, and through an annual conference. For more information, see http://www.archaeologists.net/publications.

IfA's suite of *Standards and Guidance* covers the majority of activities concerned with recovering information from the historic environment. These documents are widely used as a quality measure within the archaeology sector in the United Kingdom and further afield. The full suite of *Standards and Guidance*, along with other IfA Codes and by-laws, can be downloaded from the IfA website at http://www.archaeologists.net/codes/ifa.

IfA's technical and ethical standards underpin the practice of cultural heritage management in the United Kingdom. Its Code of Conduct and Standards and guidance provide the basis by which quality is assured across the sector through published standards for person (IfA membership, organizational registration) or for process and product (Standards and guidance).

Institute for Canine Forensics

Lynne Engelbert, Adela Morris, Barbara Pence and Dana Timbrook
Institute for Canine Forensics,
Woodside, CA, USA

Basic Information

Our Beginnings

The Institute for Canine Forensics (ICF) was established in 1997 and is a nonprofit organization located in the San Francisco Bay Area of California, USA. Our original search and rescue-based handlers were curious to learn if our dogs could find and alert on historic human remains. Dogs have been used to detect human remains for many years. Prior to the early 1990s, the capabilities of the dogs to detect the fragile scent of historic and prehistoric human burials and cremains, hundreds to thousands of years old, had barely been explored.

Our Mission

We promote and elevate professionalism in the use of specially trained canines for historic and prehistoric human remains detection.

We have developed advanced techniques using canines as an archaeological tool to assist cultural resource management firms, native tribes, universities, churches, and government agencies in the preservation of sacred human burials and cemeteries.

Our Training

A Historic Human Remains Detection (HHRD) dog is trained using old human bones, teeth, and very old cemeteries which give off a much weaker scent than that of decomposing human remains. Our dogs are trained to perform a passive alert, either a sit or down, at the strongest location of historic and prehistoric human remains scent. Searching for this weak scent requires the dog to work slowly and methodically, keeping its nose just above the ground. Our dogs are never cross-trained to detect other odors.

Intense training is required to reach certification and to maintain the skills of these very specialized teams. Training standards were developed, testing is conducted on a double-blind basis, and proctoring is done by an outside evaluator. Our handlers train several days a week, and training requirements are such that every required skill must be trained at least biannually, facilitating an ongoing certification program. Full recertification is done annually.

Utilizing Historical Human Remains Detection Dogs

Over the years we have worked with Native American tribes, forensic anthropologists, archaeologists, and other scientific disciplines to design and refine our noninvasive approach for locating historic and prehistoric human remains. We are focused on our training and search protocols and specialize specifically in detecting this very old, faint human scent.

We advocate a teamwork approach and emphasize cooperation among the multiple experts, disciplines, and agencies that we work with. Our website highlights recent projects, clients, published papers, newsletters, and news articles that are intended for networking nationally and internationally to inform and promote the exchange of new ideas and discoveries in our field.

The need to educate archaeologists in this field was critical. This is another "tool" in the archaeologists' toolbox. It is a noninvasive tool that adds another layer to the oral, written, physical, and protective efforts already used.

ICF's Practices and Procedures can be obtained upon request at info@ICFK9.org.

Major Impact

The Institute for Canine Forensics' specially trained canine teams offer a completely noninvasive method to detect historic and ancient human burials. It is a cost-effective method of locating cremations and inhumations. ICF works hand in hand with native tribes, forensic anthropologists, archaeologists, cultural resource management organizations, and other scientific disciplines and technologies.

Institute of Nautical Archaeology (INA)

Deborah Carlson
Nautical Archaeology Program (NAP), Institute of Nautical Archaeology (INA), Texas A&M University, College Station, TX, USA

The Institute of Nautical Archaeology (INA) is a 501(c)3 nonprofit research organization based in College Station, Texas, USA, and Bodrum,

Turkey. INA was founded by Dr. George F. Bass in 1972 as the American Institute of Nautical Archaeology (AINA); in 1979, the name was shortened to Institute of Nautical Archaeology (INA) to reflect its international staff and board of directors (Fig. 1). Having spent much of the 1960s pioneering the scientific underwater excavation of ancient shipwrecks in Turkey (Cape Gelidonya, Yassıada) and running an underwater section of the University Museum, with excavations in Cyprus (Kyrenia) and Italy (Porticello), Bass resigned from a faculty position at the University of Pennsylvania in 1973, and with the help of Michael Katzev, director of the Kyrenia shipwreck excavation, secured seed funding for a fledgling institute (Bass 1966, 1972). Bass served as AINA president, Katzev as vice-president, and Cynthia Eiseman as executive director.

In 1976, INA moved to Texas and affiliated with Texas A&M University (TAMU), where a graduate Nautical Archaeology Program (NAP) was established as an independent academic unit. Core NAP faculty included Bass, Donny L. Hamilton, J. Richard Steffy, and Frederick van Doorninck. In the early 1990s, sizable donations made by INA Directors and matched by TAMU led to the establishment of 8 faculty endowments and 2 student scholarships to support fieldwork and research. Today, NAP has 7 full-time faculty and ~50 graduate students completing either an M.S. in Maritime Archaeology and Conservation or a Ph.D. in Anthropology with a specialization in Nautical Archaeology. The NAP curriculum includes courses in ship design and construction, naval treatises and maritime communities, the conservation, recording, and analysis of artifacts from underwater environments, and seminars in preclassical, classical, medieval, and New World seafaring. NAP students receive field training on INA-sponsored shipwreck excavations around the world, which are directed by NAP faculty or by some of INA's more than 50 research associates. The synergistic nature of the INA-NAP relationship is evidenced by the fact that many INA research associates are NAP graduates (Hamilton 2005).

For almost 50 years, through its partnership with NAP, INA has advanced the field of underwater archaeology not only in the USA, by training future academics, museum curators, and state and federal underwater archaeologists, but also around the world, by training students from nearly two dozen countries. In North America (Bass 1988), INA archaeologists have explored or excavated shipwrecks of the Revolutionary War (*Charon*, *Defence*) and Civil War (*Denbigh*), as well as eighteenth-century merchantmen and transports (Ronson Ship, Clydesdale Plantation, Browns Ferry) and nineteenth-century steamboats (*Heroine*, Shelburne Shipyard, Yukon River). In the 1980s, INA researchers excavated two sixteenth-century Iberian shipwrecks in the Atlantic, at Highbourne Cay, Bahamas, and Molasses Reef in the Turks and Caicos. In the Caribbean, INA archaeologists have surveyed, excavated, and recorded seventeenth-century shipwrecks in Bermuda (Western Ledge Reef, *Warwick*), the Dominican Republic (Monte Cristi), and Tobago (Rockley Bay). INA archaeologists also excavated the submerged city of Port Royal, Jamaica, sunk by a massive earthquake in 1692, the Portuguese frigate *Santo Antonio de Tanna*, wrecked off the coast of Mombasa, Kenya in 1697, and the Ottoman frigate *Ertuğrul* lost in a typhoon off Kushimoto, Japan, in 1890.

INA is perhaps best known, however, for the excavation of ancient shipwrecks in the Mediterranean. Since Bass' seminal 1960 excavation of the Late Bronze Age shipwreck at Cape Gelidonya, INA archaeologists working in Turkey have excavated, conserved, studied, and published the remains of a dozen ships from the Bronze Age (Uluburun, Şeytan Deresi), Archaic Greece (Pabuç Burnu), Classical Greece (Tektaş Burnu), Hellenistic Greece (Kızılburun), as well as the Byzantine (Yassıada, Bozburun, Yenikapı), and medieval periods (Serçe Limanı). Many of these wrecks and their associated artifacts are on public display in the Bodrum Museum of

Institute of Nautical Archaeology (INA), Fig. 1 INA logo

Institute of Nautical Archaeology (INA), Fig. 2 Aerial view of INA's Bodrum Research Center in Turkey

Underwater Archaeology in southwestern Turkey (Bass 2005).

In 1995, INA opened the Bodrum Research Center (BRC), which serves as an overseas, representative office of INA in Turkey. The BRC is home to artifact and wood conservation laboratories, a dormitory and guest suite, staff offices, and a 10,000-volume research library. The BRC is staffed year-round by 20 Turkish citizens and accommodates visiting scholars, researchers, and students. In 2016, INA built and launched a 23 m (75 ft)-long archaeological research vessel named *Virazon II* which replaced *Virazon*, the 1953 US Army T-Boat that was acquired by INA in 1980 and supported many INA excavations in Turkey. INA archaeologists have also directed or codirected shipwreck surveys and excavations in Albania, the Azores, Bulgaria, Croatia, Egypt, Greece (Fourni, Danaos project), Israel, Italy (Secca di Capistello, Marzamemi), and Spain (Bajo de la Campana, Finisterre).

INA is administered by officers and a Board of Directors. INA committees provide funding annually for survey, excavation, research, and publication; in 2018, these awards totaled $125,000. INA-excavated shipwrecks are published in the Ed Rachal Nautical Archaeology Series of TAMU Press, which presently includes more than 30 titles. Interim field reports appear in the *INA Quarterly* (published since 1974) and in the monthly *INA Insider* e-newsletter, both of which are benefits of INA membership (Fig 2).

Insular Southeast Asia at the Interface of Continent-Archipelago: Geography and Chronology

Introduction

The history of human settlement in Southeast Asia, which stands at the crossroads of a huge Asian continent and multiple archipelagos that open the way to the Pacific world, is a history of geography – *lato sensu* – and of chronology. The two dimensions of time and space indeed take on a particular significance in this region, as it has been demonstrated since the great scientific revolution of the second half of the nineteenth century. Bearing testament to this, in particular, are the concurrent works of Darwin on evolution and natural selection and of Wallace on the areas of geographic distribution of living species, but also of the geologist Lyell, whose major contribution was to anchor the evolution of species in time.

This history involved multiple actors, especially during the last millions of years. Of the two principal actors, geotectonic, in particular, has modeled a chain of nascent mountains near the contact zone of tectonic plates, many of which became island arcs with or without volcanic activity. We must also take into account the major climatic cycles (alternating glacial-interglacial), which profoundly changed the morphology of the region according to the variations in sea level that could exceed 100 m. It is clear that such fundamental changes, relative to the functioning of the Earth system, resulted in a number of transformations in the landscape, in the rhythm of monsoons, and, thus, the nature and extension of ecosystems. Some were definitive, others reversible or cyclic, but all are, to varying degrees, at the origin of biogeographic situations that can be observed today, or that research seeks to reconstruct in the past.

This history is thus primarily about time, climates, and environments, punctuated by the emergence of lands, the extension of the continental shelves in turn emerging and submerging, by the establishment and the more or less long durability of contacts and corridors between the latter and the archipelagos. Evidently, and beyond the purely physical elements, the passages and biogeographic barriers were for many constituted by the expansion and fragmentation of vegetation formations, such as mangrove forests or humid tropical forests.

Humans have no more escaped the environmental constraints nor their perpetual evolution than any other living creatures. This observation seems particularly well founded with respect to the earliest phases of human settlement in these lands. Human evolution, adaptation, and endemism must thus be envisaged clearly from the biogeographic perspective that directs other naturalist studies. The genus *Homo*, however, remains a special case. Notably, due to its complex social organization, it possesses the means to adapt its technical and subsistence behaviors and to not see its existence as dependent upon the presence of a limited number of well-defined environments, as is the case for many other living beings.

The meaning of Prehistory in Southeast Asia is remarkable in many regards. Firstly, it reflects an important part in the history of the descendants of the first representatives of genus *Homo* outside of Africa, called *Homo erectus* in Asia. Having travelled in the southern part of Eurasia, these hominids, for the first time, crossed the Equator southward. They were also the first, in the history of humanity, to become islanders.

But this Paleolithic human adventure in Southeast Asia, so strongly influenced by its biological as much as its geographical context, still recounts and holds numerous events associated to the

emergence of endemic forms of hominids. Researchers give them a special taxonomic status and see the coexistence, even the cohabitation, of groups intended for near extinction with the first *Homo sapiens* who conquered the archipelagos. They also ascribe to the *Homo sapiens* the command of natural processes such as the "taming" of animals and useful plants, which probably developed in a very early way in the archipelagos.

Definition

Although research, notably since the 2000s, has seen a revival in activity in continental Southeast Asia, the majority of data relating to the earliest phases of Prehistoric chronology concentrates on the archipelagos connected to the Sunda plateau (Fig. 1a), i.e., the southeastern end of Eurasia, partly submerged today by shallow seas (the South China Sea, the Java Sea).

Along the Sunda block, which includes the large western Indonesian islands (Sumatra, Java, and Borneo), the Malay and Indochinese peninsula as well as Thailand, island arcs (external non-volcanic arc, internal volcanic arc) mark the subduction zone of the Australia-Indian Ocean plate under the Eurasian plate. To the southeast lies the Sahul shelf, which includes New Guinea and Australia. Finally, the northeastern region, which includes the island of Sulawesi, the islands of eastern Indonesia, and the Philippine archipelago, is marked by a very complex geotectonic activity, particularly bringing into play the Philippine and Pacific plates.

This configuration is partly the origin of the biogeographic provinces such as Wallacea. The latter is limited to the east of the Sunda block by the Wallace Line, passing through the Makassar Strait, which connects the Celebes and Java seas. Measuring only about 15 km in its width, this straight can reach depths of more than 2,000 m.

Geotectonic activity is extremely important, as indicated by the speed at which plates can move, as this can exceed 10 cm/year, as well as the large number of still active volcanoes. It is within the context of this dynamic interplay that we need to consider the different phases of settlement across the region: For example, the internal volcanic arc of Sunda (Fig. 1a), which includes the island of Java, has most likely functioned in its current configuration for the last 2 million years (Ma). The vast majority of ancient fossil sites are linked to its activity.

The intention here is to cover the largest part of the Quaternary, beginning with the Gelasian, around 2.6 Ma, naturally considered under the aspect of climate chronology, which best illuminates the changing geography of the region. This is particularly demonstrated by the establishment of cycles of duration close to 100,000 years at the beginning of the Middle Pleistocene (c. 0.8 Ma). A climatic optimum and high sea levels are found at the beginning of the Upper Pleistocene (which begins around 130,000 years, at the isotopic stage 5 -MIS 5 – of the marine isotopic chronology). The regional "Paleolithic" continues into the Holocene (well after the deadline conventionally set at 11,700 years).

These classic boundaries take on all their meaning here, because the eustatic oscillations are linked to them. Within the order of a few tens of meters in the Lower Pleistocene, they were able to reach 120 m as early as the beginning of the Middle Pleistocene (Fig. 1b). The geographic consequences were immense, affecting the land surface (the opening of land bridges connecting the islands, connecting the archipelagos to the mainland) as much as the volume of water subject to evaporation in the intertropical zone, hence clearly influencing precipitation.

Historical Background

The sites involved mainly include:

- In the areas with high tectonic and volcanic activity, or high subsidence, thick (volcano-) sedimentary series, as is the case on the island of Java (Fig. 2a).
- Alluvial systems formed along the major rivers which, it must be noted, are often more favorable to the conservation of stone tools than

fossils, whether they are alluvial terraces or flood plain deposits. These alluvial systems are equally found in mainland Southeast Asia (Mekong and Irrawady valleys (Fig. 1a)) as in the islands (the archipelagos of Indonesia and the Philippines).

- Karstic massifs, widely represented, within which a number of types of deposits can be found, such as classic cave fillings (Fig. 3), with their sediment having undergone some solifluxion or even been transported by the racking at a lower level of the karst; alluvial deposits trapped in the cavities; archaeological soils under porches, positioned as rockshelters; fillings of fissures and accumulation of fossils where often one can discover mainly teeth because of the destructive activity of hystricidés (porcupine), these last fillings being able to be cemented in breccias etc.

The Ape-Man of the Sunda Islands

Human paleontology was, in fact, born in Southeast Asia in the late nineteenth century. The historical context of research has thus been guided, since its inception, by the search for human fossils. Influenced by the ideas of Darwin and Wallace as professed by Ernst Haeckel, the Dutch medical anthropologist Eugene Dubois undertook, as early as 1887, research in Sumatra of the "missing link" between an ape ancestor and a human, known to have lived in the forests which are now home to the great anthropoid apes such as *Pongo* (derived from the name "orangutan," meaning the man of the forest in Malay). Only a few discoveries of Neanderthals were known – and debated – at the time.

These first discoveries of fossils – notably elephants – in the caves of the island demonstrated, to the eyes of the European scientific community, that a passage really existed in the past between the islands and the continent. Dubois was then notified of the discovery, in a karst massif in eastern Java (Wajak near Tulungagung (Fig. 2b)), of a highly mineralized skull which proved to belong to our species, *Homo sapiens*.

Later on, he drew inspiration from the recounting, in classic Javanese literature, of the discovery of many bone fossils in sedimentary horizons associated with the chain of hills known as Kendeng (Fig. 2a), which crosses the central and eastern parts of the island from west to east.

These fossils were related to the remains of victims of the great mythical battles in the Hindu tradition. The Javanese painter Raden Saleh (1811–1880), who spent a long time in Europe,

Insular Southeast Asia at the Interface of Continent-Archipelago: Geography and Chronology, Fig. 3 The cave of Song Terus (Java). (© Centre archéologique national d'Indonésie et Muséum national d'histoire naturelle)

even organized excavations near Kedung Brubus. He subsequently sent his discoveries to Karl Martin, a Dutch geologist, who had already noted the relatedness with the Indian fossil deposits of the Siwaliks, in the foothills of the Himalayas, where Richard Lydekker had described a maxillary ape.

Between 1889 and 1891, Dubois also discovered a fragment of human mandible at Kedung Brubus, then during extensive excavations on the site of Trinil (Fig. 4), in ancient volcano-sedimentary layers, a skullcap (first attributed to a gibbon), and then a human femur. In 1894, Dubois published the discovery of *Pithecanthropus erectus*, human's ancestor, and the fossil of Trinil (conserved in the NCB Naturalis in Leiden) since became the holotype of *Homo erectus*.

(**b**) The femur of *Pithecanthropus erectus*. (**c**) Reconstitution of "Pithecanthropus" from Java by Eugène Dubois in 1900 (Documents NCB Naturalis, Leiden)

Multiple Paleoanthropological Discoveries

Homo erectus

The heated debates that followed the publication of Dubois aroused new research, directly in Southeast Asia as well as in other regions. The first half of the twentieth century thus saw the rise of diverse hominid taxons, such as *Australopithecus africanus* (1924) and *Sinanthropus pekinensis* (1926, Chinese *Homo erectus.)*. Naturally, research intensified in Southeast Asia.

In Java, the Dutch colonial office of mining research encouraged some of its members to continue work on stratigraphy and paleontology, and recruited someone who would become one of the major figures of human paleontology and prehistory in Southeast Asia, Ralph von Koenigswald. Thus were brought to light, in east Java, during the

1930s, human fossils of the Solo river, near Ngandong (a series of 11 skullcaps associated with some postcranial fragments, whose brain is much more developed than the fossil of Trinil, Grimaud-Hervé 1997) and also the Mojokerto juvenile skull.

During the same period, Von Koenigswald initiated his surveys in the Sangiran dome (Central Java), which much later (1996) became included on the World Heritage List. He discovered, within a few years, the first reference points for a series of *Homo erectus* ranging along the Lower Pleistocene, including the most robust and archaic fossils, originally called *Meganthropus palaeojavanicus*, such as Sangiran 4 and Sangiran 31 (Fig. 5c) and of the Middle Pleistocene (fossils similar to the Trinil specimen, such as Sangiran 2 and Sangiran 17 (Fig. 5a)).

It is in this way that very rapidly, the island of Java alone brought information on the very long existence of the taxon *Homo erectus* in island environments. Several sites have been discovered since the Second World War (Pati-Ayam, Sambungmacan, Ngawi, Miri, Semedo). The current dates place the totality of fossils between 1.5 Ma (the most archaic fossils of Sangiran, Mojokerto) and the end of the Middle Pleistocene (or even the first half of the Upper Pleistocene for the late *Homo erectus* of the Solo river, of Ngawi and Sambungmacan (Fig. 5b)). Between these two groups a homogenous population (nearly 50% of the inventory known) takes place, whose characteristics are very similar to those of the holotype, which dates from the late Lower Pleistocene and early Middle Pleistocene (near 0.8 Ma).

It is natural that the paleoanthropological record is not as developed east of the Wallace Line (Bellwood 2007), although archaeological evidence of human presence exists (it was probably *Homo erectus* who crossed the filter of the straits during periods of very low sea level at the beginning of the Middle Pleistocene, Morwood et al. 1999). They were the possible ancestors of *Homo floresiensis* (Fig. 5d (cf. *infra*)). More surprisingly, the exploration activity in mainland Southeast Asia, and notably in the Indochinese peninsula, was not successful despite the active search for old human fossils since the beginning of the twentieth century. Only very fragmentary remains, whose nature or stratigraphic position remains contested, were published (Zeitoun et al. 2008). The "best" reference point between the

Insular Southeast Asia at the Interface of Continent-Archipelago: Geography and Chronology,

"*Sinanthropus*" and the "*Pithecanthropus*" remains the presence of teeth (cf. *Homo erectus*) discovered in the breach of the Tham Khuyen cave in North Vietnam, in Lang Son province near the Chinese border, dated to around 0.5 Ma, and in Thum Wiman Nakin (in the center-north of Thailand, probably toward the end of the Middle Pleistocene).

Homo Sapiens, But Also Other Humankinds?

Homo sapiens, which were probably the only hominids to have, thanks to their social organization, the ability to organize ferry crossings, populated Australia in the Upper Pleistocene, more than 50 ka ago (O'Connell and Allen 2004). The research of their traces in mainland and island Southeast Asia thus represents a challenge for researchers. Sites appear scattered throughout the zone. Among the most famous discoveries, from a historical perspective, are those of Wajak (East Java), Niah (*deep skull*, Sarawak, Borneo, whose ancient age – c. 40 ka – has been recently confirmed, Barker et al. 2007), Moh Khiew (Thailand, Malaysian peninsula, around 28 ka), and Tabon (Palawan, Philippines, Dizon et al. 2002 (Fig. 6)), of which some fossils

seem associated with archaeological horizons older than 30 ka.

Beyond the discoveries or new fossil studies, at stake is the anatomic and taxonomic characterization of those which are not directly related to Homo sapiens (late *H. erectus* or endemic forms) as well as their precise dating (Yokoyama et al. 2008). The latter depends on the establishment of a convergence between, on the one hand, direct analyses, such as ^{14}C dating, uranium series (U/Th), combined analyses by uranium series/electron spin resonance (ESR), which often open a debate on the model of incorporation of uranium or about the meaning of dosimetric measures in the environment, and on the other hand, analyses carried out on their context (^{14}C, OSL, ESR etc.).

All fossils dating from 100 ka until the first part of the Holocene (before 6,000 years) reflect the rare elements of a puzzle which corresponds to a possible early arrival of our species in Southeast Asia (from southern China to the archipelagos). Its expansion took place during the second part of the Upper Pleistocene (including the recent discovery of Tam Pa Ling in Laos, c. 46 ka, Bacon et al. 2012) and the last glacial maximum (LGM). Then, a redistribution of groups occurred during the rise of sea levels at the beginning of the Holocene (Détroit 2002).

Also included in this fossil register are the remarkable discoveries published in the last few years, concerning the sites of the Upper Pleistocene such as that of *Homo floresiensis* (Liang Bua, Flores, Morwood et al. 2004) or that of Callao cave, in the north of the island of Luzon, in the Philippine archipelago, whose metatarsal would come within the limits of morphological and dimensional variability of *Homo habilis* and *Homo floresiensis*.

With the oldest fossils reputed to belong to the *Homo sapiens* species, these last discoveries open a debate relating to the coexistence, particularly in island environments, of the last *Homo erectus* and the first *Homo sapiens*.

Humans and Animals

The separation between biogeographic provinces of Indochina and Sunda takes place at the level of the Isthmus of Kra (Fig. 1a), a barrier which could have had a southern position before the Upper Pleistocene (Tougard 2001).

Since the beginning of research in the islands of Southeast Asia, it appears that the understanding of complex phenomena that led to the colonization of the region by the hominids, from the chronological as well as the paleoenvironmental aspects, passed by the interpretation of associated fauna, most notably continental mammals.

The dispersals of these mammals seem to have followed two routes according to the period, the route called Siva-Malayan (India-Malaysia) and the one called Sino-Malayan (China-Malaysia). These migrations have so far never included, for obvious paleoenvironmental reasons, families such as the equine, camelids, or giraffidae.

According to the period and the degree of exondation on the plateau, the animals were able to reach the archipelagos either by chance, or by crossing modest straits, or by way of real corridors. Dispersals and endemism were thus responsible of the nature of fossil assemblages in the deposits.

The first biostratigraphic schemes established before absolute dating methods were implemented, distinguished, in Java: Lower, Middle, and Upper Pleistocene, in the form of a classic triptych created by von Koenigswald and including fauna called Djetis, Trinil, and Ngandong. Stemming from stratigraphic localities discovered in East Java, these associations applied to sites in central Java were used to define the stratigraphy of the sites such as the dome of Sangiran (which, in turn, used until recently the toponyms of the eastern part of the island: formations of Pucangan, Kabuh and Notopuro).

The 1980s allowed for the reevaluation of this biostratigraphy by taking into account the paleobiogeographic aspects (de Vos et al. 1982) and definition of several horizons, named:

- Satir, near Bumiayu (central Java), typical island fauna including the *Mastodon* (c. 1.5–2 Ma)
- Ci Saat (same region), later in the Lower Pleistocene (Fig. 7), but reflecting the arrival of carnivores, of *Stegodon* and probably *Homo erectus*

I

Insular Southeast Asia at the Interface of Continent-Archipelago: Geography and Chronology, Fig. 7 Hexaprotodon sivalensis (Sangiran, Java, c. 1.2 Ma). (**a**) Original fossil. (**b**) Reconstitution of the hippopotamus after casting. (© Centre archéologique national d'Indonésie et Muséum national d'histoire naturelle)

- Endemic fauna of Trinil, dating from the end of the Lower Pleistocene
- The association of Kedung Brubus, at the very beginning of the Middle Pleistocene (large exchanges with the continent, marked notably by the arrival of *Elephas*), followed toward the end of this period by the Ngandong fauna
- The fauna of Punung (beginning of the Upper Pleistocene), including species adapted to the tropical rainforest (such as *Pongo*, *Helarctos* and *Symphalangus*).

These horizons, with the exception of the fauna of Punung, mainly reflect an Indian origin until the beginning the Upper Pleistocene.

The situation becomes more complex for the islands located to the East of the Wallace line, sometimes due to a lack of documentation on the faunal groups themselves (either in representativeness, or from a chronological point of view), but more often because of the evident multiplicity and the complexity of the dispersal events. In fact, in these islands, evolution was often synonymous with endemism as was the case for the fauna of Sulawesi, or of relative poverty, like in the Philippines, which deliver, in a remarkable fashion, dwarf forms.

A Cultural Register to Construct

The archaeological aspect of the regional Paleolithic is considered in the context of another entry in this volume, but it is important to note here that a number of available reference points have been discovered since the beginning of the twentieth century. Von Koenigswald was in this regard a pioneer in his quest for the culture of the "*Pithecanthropus*" of Java, which he searched for, in the 1930s, in the chains of hills surrounding sedimentary basins where fossils were found. He thus brought to light the lithic assemblage of Patjitan (Fig. 2b), in the Southern Mountains of Java, as well as a small flake industry in the dome of Sangiran. Other discoveries followed, emphasizing the succession of migrations from the mainland to the islands, and between the islands themselves. The chronology of this story is still the subject of debates. Among the latter are the discoveries, in the 1950s–1970s, of the Cabalwanien, which was identified north of the island of Luzon (possible relation with fossils of the Middle Pleistocene) and Theodor Verhoeven's finds in Flores (Eastern Indonesia), which have

contributed to revealing that *Homo erectus* was able to cross the Wallace line from west to east.

Key Issues and Current Debates

Current Challenges Linked to Human Evolution

These issues were, for the most part, outlined above and remain a central concern of researchers (Widianto and Simanjuntak 2010):

- It is striking to note that the age of the first islanders (c. 1.5 Ma) is only slightly younger than the age of the most ancient fossils known outside of Africa (e.g., Dmanisi, Georgia) and that the oldest island *Homo erectus* present quite specific characteristics (cf. notably the robustness of the mandicatory system), whose connection with a possible adaption in colonized environments would be appropriate to study.
- Exchanges with mainland Asia occurred during different periods, in the same way for humans as for fauna, and were particularly intense at the dawn of the Middle Pleistocene. At this time, the hominids were probably able to cross, with several faunal taxa, the Wallace line. However, the fossil register of the Southeast Asian mainland is almost nonexistent and no human fossil has yet been unearthed in eastern Indonesia. Comparative studies, either between mainland and island *Homo erectus*, or within the register of *Homo erectus* dating between 1 Ma and 0.7 Ma in island environments, should make it possible to find traces of these mainland-archipelago contacts (Kaifu et al. 2008).
- The end of the middle Pleistocene and the Upper Pleistocene also poses important questions about the causes of extinction for the latest *Homo erectus* (a phenomenon no doubt comparable, in certain respects to the extinction of the Neanderthal lineage in Western Europe). This extinction should be seen in parallel with the arrival of the first modern humans and also with the evolution of particular forms of hominids (cf. *Homo floresiensis*).
- Finally, there now exists a scientific synergy between different regional scientific programs, which can identify the mosaic of developed settlements since the beginning of the Holocene in the region, after the sharp rise in sea level that completely reallocated the territories.

Stratigraphy and Geochronology

These disciplines aim to describe the context of the distribution of hominids and the major archaeological sites, for which (cf. *infra*) the resolution power of biostratigraphy is insufficient. The long stratigraphic references are few and, for many, draw on fundamental work carried out before the Second World War. The precision of the chronological framework today involves the implementation of diverse methods, including the following:

- Paleomagnetism.
- Argon, fission tracks or luminescence (OSL) methods when volcanic effluents are present and we can evaluate the penecontemporaneity of the analyzed material and of the sedimentary matrix. This is not always the case in very actively volcanic regions, where deposits regularly reshuffle older volcanic elements, stemming from the volcanic cones themselves.
- ESR dating on quartz grains bleached by sunlight and combined U/Th- ESR analyses on fossil teeth.
- For more recent times, particularly in karst environments, the dating of speleothems (U/Th) and radiocarbon can be added.

The progress achieved in recent decades provides more accurate chronologies, but the complexity of the dynamics of the deposits (cf. example of volcanic effluents above) involves the simultaneous implementation of all possible methods.

The Reconstruction of Landscapes

The major goal is here to identify, in the sedimentary and diagenetic dynamics, the climatic events that have affected the region. The phases of expansion and fragmentation of the forest have had a very important impact on the evolution and

behavior of hominids and are linked, beyond climate change, to the tectonic (synorogenic erosion) and volcanic (the overload of rivers with eruptive material) evolution of the region (Sémah et al. 2001).

Beyond these classic sedimentological descriptions, paleobotany (continuous pollen records (Fig. 8) and phytoliths study) is combined with paleopedology (micromorphological analyses addressing shorter periods clearly more scattered in time).

The records enable to follow the progressive emersion of reliefs in Java (the filling of lagoons, the development of mangrove forest) as well as the dynamic distribution of vegetal formations. In this way, it appears that the tropical rain forest dominated during the Lower Pleistocene, even though it was subject to repetitive destructions because of volcanic eruptions. The opening of the landscape during "glacial" periods (especially during the Middle Pleistocene) restricted the rain forest to galleries along the watercourses. At certain times (marked by pedogenic formations), the fragmentation of the forest could even leave room for open, savannah-like patches. These "dry" episodes are underlined by the importance of sedimentation phases, the opening of the forest allowing more severe erosion during the rainy season (seasonality persisted during "glacial" periods).

At the regional level, the reconstruction of the landscapes that may have existed on the Sunda shelf during the maximum exondation (e.g., beginning of the Middle Pleistocene and LGM) is crucial to provide us with information about the migration of fauna and hominids. Particularly

Insular Southeast Asia at the Interface of Continent-Archipelago: Geography and Chronology, Fig. 8 Vegetal Paleoenvironments of the Sangiran Dome (Java). *1* Kalibeng – yellow marl. *2* Kalibeng – blue clay. *3* Transition limestone. *4* Lower Lahar. *5* Pucangan – black clay. *6* Diatomites. *7* Tuf. *8* Grenzbank. *9* Kabuh. *10* Notopuro – upper Lahar. *11* Terraces. (**a**) Mangrove. (**b**) Swampy forest. (**c**) Rainforest. (**d**) Seasonal forest. (**e**) Savannah. According to pollen studies (A.-M. Sémah). (Photographs: A.-M. Sémah)

here, the hypothesis on the past existence of a "savannah corridor," which might have developed along the principal rivers draining the waters from the great massifs of Java, Borneo, and Sumatra, favoring migrations in this way, awaits confirmation. Similarly, the description of the intense development phases of the rainforest (MIS 5–125 ka, Holocene climatic optimum around 8 ka) is also fundamental to understanding human migrations.

The Biostratigraphic Framework and the Meaning of Taphonomic Assemblages

The study of vertebrate faunas has been the object of a special effort. The current landmarks in Java can be qualified as solid. In fact, they are based on collections harvested with a good stratigraphic control and an approach that is in line with the regional naturalists' concerns: integrating paleoecological reconstructions, phenomena of dispersals and migration, adaptation as well as evolution in isolated environments (endemism, vicariance). Their results are coherent with the climatic and paleoecological history of the region, particularly demonstrating (de Vos et al. 1994):

- Narrow passages to the south and southeast of the Sunda shelf during the Lower Pleistocene
- More sustained exchanges with the mainland during the installation of the climatic conditions of the Middle Pleistocene (climatic contrasts actually started with the MIS22 stage (Sémah and Sémah 2012), c. 0.9 Ma) when major climatic cycles acquired a length of about 100 ka
- Significant changes in the composition of faunal assemblages during the Upper Pleistocene, with an association perfectly adapted to the rainforest during stage MIS 5, then relative impoverishment of fauna during the last glacial maximum, followed by a new adaptation to a forest environment at the beginning of the Holocene

These landmarks, however, constitute only an incomplete framework that requires the reconstruction of its history with a temporal resolution as fine as possible: Only ongoing fieldwork can bring an answer here, by developing and using a register backed up by statistically representative collections (Moigne et al. 2004). Similarly, the nature of the relationship between the archipelagos on both sides of the Wallace Line (van den Bergh et al. 2001) should be described more accurately, for example, with regard to the number and duration of endemic periods in Sulawesi (an island which occupies a central place in the zone under study) and the different routes which facilitated colonization of the Philippine archipelago (passage from south toward the north via Borneo and the Palawan ridge or passage via the chain of southern islands near Mindanao). Comparative research between Pleistocene fossils in the Indochinese and Sunda provinces is now starting to produce a dynamic vision of their borders, suggesting in particular the late onset of the Isthmus of Kra operating as a biogeographic barrier during the Quaternary.

Such results are fundamental to understanding the ecological constraints which weighed on human groups and animals (animals' level of dependence on ecosystems being higher).

Modern methods of taphonomic study are developing today in Southeast Asia. They help to better understand the significance of collected palaeontological assemblages, and also illustrate, in the archaeological horizons or those that are derived from them, the behavior of the hominids with respect to their faunal environment.

International Perspectives

Beyond the concern to conduct research at the international level, the focus on conservation is certainly a major issue at all levels. Multiple factors related to the limited number of researchers or the difficulties of the terrain mean that the sites of Southeast Asia are still very far from having been discovered or exploited to their true value. Sites that are known, sometimes for over a century, have shown all the potential that further research may still bring to their interpretation.

International meetings organized under the auspices of UNESCO clearly show that there are few properties that meet all the criteria required

for registration, either through the World Heritage framework or through more thematic programs.

The direct access to scientific information is often put in danger:

- At the level of sites, due to the mere fact of very active erosion in tropical region and of significant development (e.g., public infrastructures) carried out there
- At the level of movable heritage, through the great dispersion of collections

Objects and data collected during the colonial era, for example, are scattered within museums in many countries. However, some states still lack the resources for heritage management, which underlines the international responsibility on the matter. Initiatives taken by regional governments should thus be optimized by a genuine dynamic cooperation, allowing for the sharing of experience and access to data, which have a significant impact on foreseeing the scientific research programs.

This perspective of conservation cannot be separated, in the long term, from questions relating to the preservation of ecosystems and the biodiversity in a zone not only subjected to important development initiatives, but also to a number of major risks, including global climate change.

It is important to complement this reflection on the preservation of existing environments with the memory of an exceptional history, built over nearly a million and a half years ago by conquest, migration, coexistence, adaptation, or resilience of different groups of hominids.

Future Directions

Southeast Asia, when considered as a bridge between mainland and archipelagos, represents a fantastic natural laboratory for the study of biodiversity, as much in its current configuration as in the long term, within which human adventure plays a very special part.

Expected orientations for research involve the integrated construction of an interdisciplinary framework, which would definitely place human evolution (*lato sensu*) within a naturalist and cultural perspective. As such, there is much to be expected from the development of archaeological research in a real paleobiogeographic perspective, including from the cross-sectoral perspective of linking prehistory to biology. The chronological approach to the fragmentation of the rainforest, for example, as a result of climate forcings, could explain the diversification of some populations, or initiate new hypotheses on some speciation. A similar approach can be implemented, in coastal areas, by identifying in the records the oscillations of sea level. In contrast, work on the biological diversification based on current populations could help interpret some human replacements recorded on prehistoric sites.

The desired effect of synergy should thus result from the intersection of data relating to the evolution of climate and of environments, as indicated by mineral, biological and cultural markers in the sedimentary records, with data provided by diverse approaches of extant populations on the other hand (analysis of patterns of endemism, of population and habitat fragmentation, and cytogenetic studies).

State of Knowledge and Current Debates

Introduction

Since the end of the nineteenth century, the "Pithecanthropus" of Java (*Homo erectus*) profoundly marked the history of science and

definitively rooted Southeast Asian prehistory in a paleobiogeographic perspective (Fig. 1).

Any approach to the Paleolithic period is thus linked to issues of adaptation to the different natural environments encountered by hominids. The latter, evidently, followed identical migration routes to those of continental vertebrate fauna originating from the Asian mainland whose affinities, according to the period, were Indian or Chinese.

One of the major issues that arise is, of course, distinguishing a possible "human" special feature within these episodes of dispersion which, for the most recent periods, reflect an organization that allows the use of the term "migration." Resolving this question involves the study, and then the connection, of several archaeological records appropriately integrated into the paleoenvironmental framework.

However, it should be recognized that only around a dozen or more suitably documented records are available, a number which should be seen within the context of the immensity of the region under consideration (more than 20 million km^2). The sites under investigation are moreover spread over a history which began in the Lower Pleistocene, some 1.5 Ma ago, with the arrival on the island of Java of the first islander in the history of humanity, and which ended with the dissemination of Neolithic traditions coming from continental Asia in the archipelagos a few thousand years ago.

This history has featured successively but also sometimes concomitantly:

- *Homo erectus* belonging to very different groups: the latest forms from the Solo River, which were extinct at the end of the Middle Pleistocene (or according to some).
- Researchers, during the Upper Pleistocene, differ considerably from robust and archaic forms of the Lower Pleistocene (see "Meganthropus"); these *Homo erectus* were able, on certain occasions, to cross biogeographic boundaries as shown by the early population on the island of Flores in East Indonesia.
- *Homo sapiens* distributed between (1) the very first immigrants who could have arrived in the region at the beginning of the Upper Pleistocene; (2) populations who occupied not only

Insular Southeast Asia in the Lower Paleolithic, Fig. 1 The islands of Southeast Asia, map of localization of sites

the Indochinese province but the entire Sunda region, emerged during the Last Glacial Maximum, and spread across it owing to the creation of vast zones of circulation on the subcontinent; and (3) groups which occupied the islands during the great geographic upheaval which took place at the beginning of the Holocene, with the submersion of vast stretches of the mainland.
- Other hominids (see *Homo floresiensis*), still mysterious in many respects, stemming from a very localized endemic evolution, which could not have occurred on the island of Flores alone.

Faced with such geographic, chronological, and evolutionary diversity, the few available archaeological records today must certainly be treated with caution, without relinquishing the pursuit of research on how their characteristics may reflect a regional phenomenon.

Definition

It seems relatively easy to speak of the "Lower" Paleolithic in the islands of Southeast Asia, the use of the term being made easier when the archaeological discoveries were linked to a context where only *Homo erectus* would have been able to intervene. In the current state of research, this qualifier can be used for sites dating to the Lower Pleistocene and the Middle Pleistocene.

By contrast, going further in the periodization proves to be very tricky. Earliest attempts at subdividing the prehistory of Southeast Asia, whose mosaic characteristics appear more evident every day, or constructing a cultural chronology similar to that of Western Europe, have proved erroneous and unsuccessful. It is thus appropriate here to banish the terms "Middle Paleolithic," "Upper Paleolithic," or "Mesolithic," which, by the way, often pose problems for researchers: thus, the frequent usage, for lack of a better term, of "preneolithic" can be found to describe some features from the beginning of the Holocene and prior to contact with Austronesian groups or with other carriers of Neolithic traditions.

Rather than end with a "periodization," the current work has thus as its principal aims:

- To clearly show the relationship between an archaeological horizon and a particular hominid (a sometimes difficult task during the first part of the Upper Pleistocene)
- To search for solid chronological records to better situate the wide diffusion of practices such as the development of habitats in caves or the systematic use of fire
- To stress important innovations linked to *Homo sapiens*, such as the construction of sophisticated tools in hard animal materials, the concretization of symbolic behaviors, or even the practice of organized sea crossings

Thus, in the present article, the upper chronological limit of the corpus will remain somewhat vaguely defined, but in order to reflect the current state of research and its orientation, it will mention several deposits in the second half of the Upper Pleistocene.

In such a configuration, a number of archaeological assemblages retain from the time of their discovery a name based on a toponym. Rare are those that, following the example of Hoabinhian discovered on the continent (North Vietnam), represent a regionally meaningful cultural facies.

Following the example of Anyathian defined in the Irrawaddy valley in Burma, we also speak of "Patjitanian," "Cabengian," or "Cabalwanian" in the Southeast Asian islands. These designations do not contribute substantially to studies, and the latter must focus rather on the meaning of assemblages in given geographic and paleoecological contexts.

It is necessary to recall in the last resort that in Southeast Asia, and perhaps more than anywhere else, the description of "Paleolithic" features should not refer to only stone tools, which unfortunately are often the only ones preserved, particularly in alluvial sites which are the most frequent. Although the technical and subsistence strategies of human groups would naturally use

lithic materials whenever available, it is far from being the only one used. Several publications have, for example, evoked the importance since the Paleolithic of bamboo, almost ubiquitous grass trees.

Historical Framework

Interest in the behavior of hominids in insular Southeast Asia has been aroused since the end of the nineteenth century with the discovery by Dubois of the *Pithecanthropus erectus* (today the holotype of *Homo erectus*). The reconstruction presented by the discoverer during the Exposition Universelle in Paris in 1900 shows this hominid looking intently at the tool he is holding in his right hand.

However, during this time, the archaeologists working in the Indonesian and Philippine archipelagos mainly concentrated their attention on the tools that appeared the most meaningful, such as polished Neolithic axes. Neither the initial excavations at Trinil site (Fig. 2b) nor those developed at the beginning of the 1900s, during the great pluridisciplinary expedition of Selenka, were able to draw sufficient attention to the taphonomy of the explored horizons, and many behavioral data may thus have escaped the researchers.

At the end of the 1920s, Ralph von Koenigswald very quickly associated the search for artifacts with his paleontological and paleoanthropological work in Java. As a result he discovered, in the upper valley of the Baksoka River (in the Southern Mountains of eastern Java), the so-called Patjitanian industry (Fig. 3b, c) on pebbles and large flakes (Bartstra 1976), which, being encouraged in this direction by Pierre Teilhard de Chardin, he was to attribute to *Homo erectus*. Similarly, he highlighted an industry of small flakes in the Sangiran dome (in the center of the island of Java, the richest site of hominids in Indonesia), called the "Sangiran flakes," the majority of which is made of allochthonous rocks, coming from the Southern Mountains of Java (von Koenigswald and Gosh 1973).

Robert van Heekeren, in his review of the prehistory of Indonesia in 1957, also mentioned the isolated discovery of bolas at the Sangiran site and described several pieces (including a bone industry) recovered in the eastern part of Java (Watualang), renowned for being contemporary to the "Solo river Men". However, the lack of documentation on the context of these objects does not permit any firm correlation with the site of Ngangdong, which yielded 11 fossils (mostly skullcaps) of derived *Homo erectus* (nevertheless, the presence of bolas in the sedimentary horizons excavated at this time in Ngangdong has now been proven).

The discoveries have multiplied in Indonesia and the Philippines (Figs. 1, 2a/c, 3a, and 4a–e) since the end of the Second World War, particularly with the characterization of Cabalwanian pebble tools in Cagayan Valley in the north of the island of Luzon, but also with the find of pebble tools and flakes in the collection assembled during the 1920s by Henry O. Beyer in the southern part of the island, or even with the industry of Cabenge discovered in the valley of Walanae in Sulawesi. Owing to the difficulty in obtaining radiometric dating at the time, their age gave rise to debates, often poorly argued, in the scientific literature, sometimes making a similar techno-complex oscillate between the Lower Pleistocene and the start beginning of the Holocene!

These discoveries were also addressed, in a quasi-systematic way, by taking into account the theory of Hallam Leonard Movius (1944), according to which east Eurasia stood out as much by the absence of bifaces as by the persistence of choppers and chopping tools. It is not possible here to address the question in detail, but rather than the controversy surrounding the "Movius Line" for several decades, one must remember that the reflections that it aroused on the meaning of the lithic assemblages proved rewarding at the level of Eurasian prehistory as a whole.

The Hoabinhien was brought to light as early as the 1920s in the eponymous province of North Vietnam by Madeleine Colani and then accepted as characteristic Paleolithic during the 1st Congre's pre'historique d'Extrême-Orient in Hanoi in 1932. Its extension toward the archipelagos was

Insular Southeast Asia in the Lower Paleolithic, Fig. 2 (**a**) Detailed localization of sites. (**a**) Flores, (**b**) Sumatra, (**c**) Philippine Archipelago. (**b**) Location of sites in Java. recognized by Pieter Vincent van Stein Callenfels, highlighting the numerous "sumatralithes" (unifacial pebble tools) in the shell middens in the north of Sumatra.

Finally, it is worth recalling, sidelining the subject of the "Lower Paleolithic" discussed here, that the archaeological record recognized at an early stage includes characteristics formerly called

Insular Southeast Asia in the Lower Paleolithic, Fig. 3 Hand axes of Indonesia and the Philippines. (**a**) Arubo (Luzon, Philippines), (**b**) Koboran (Punung, Pacitan, Indonesia), (**c**) Baksoka River (Pacitan, Indonesia) (© **a** Alfred Pawlik; © **b**, **c** Centre archéologique national d'Indonésie et Muséum national d'histoire naturelle)

"Mesolithic." Indeed the van Stein Callenfels' excavations in Sampung Cave in East Java grounded the research concerning the beginning of the Holocene period during the first half of the twentieth century. Although the reduction by-products were not collected then, in preference for more elaborated pieces, the Sampung site marks, however, the era during which the importance of man-environment relationships in the prehistory of the archipelagos was highlighted. This site has shown the emergence of an industry made on hard animal materials and enabled the first description of fauna from this period, which would become the subject of several studies developed today.

Major Questions or Debates

The Question of Origins

Many discoveries, mainly in alluvial formations, can be described as "Lower Paleolithic." However, because of the weakness – or lack – of stratigraphic control, debates about their age most of the time prevent accurately situating the arrival of the first islanders during the Lower Pleistocene. At Bukit Bunuh, in the Lenggong Valley (Malaysian peninsula site), the presence of knapped lithic elements dating to a very ancient period (1.8 Ma) has been indicated, but, nonetheless, characterizing these pieces is tricky due to discoveries their position trapped in a breach of

impact (suevite). The same authors subsequently described an assemblage on this site dating between around 300 and 600 ka.

The site that has yielded the greatest number of "archaic" *Homo erectus* is to this day the Sangiran dome, at the center of Java. These are associated

Insular Southeast Asia in the Lower Paleolithic, Fig. 4 Artifacts from the Lower Paleolithic in the Philippines. (**a**, **b**) Cagayan (Luzon), (**c**–**e**) Cagayan de Oro (Mindanao) (© University of the Philippines – ASP)

with fossil-bearing sedimentary layers (called Pucangan or Sangiran, dated between 1.8 and 1 Ma) primarily deposited in marshy environments, and where no archaeological horizon (in place or reworked) could be observed.

Only rare behavioral clues have been published on these first islanders, relating to marks on fossil bones that may have possibly been linked to the use of tools made of shell or to the analysis of dental micro-erosion of hominid fossils.

It is toward the end of this Pucangan period, that, in the mid-2000s, several "Sangiran flakes" were discovered in conglomerate lenses at the Dayu site; they are today the oldest lithic artifacts known in Java (Widianto 2006). The latter are also found in the upper conglomeratic layers which mark the end of the Upper Pleistocene (Grenzbank zone of von Koenigswald). The Grenzbank largely corresponds to the synorogenic erosion deposits linked to the last uplift of the hills ranges which frame the Solo depression (Kendeng hills to the north and Southern Mountains). It is expected, considering the deposition environment, that the flakes present the patina and wear linked to fluvial transport. Naturally, their size is identical to that of the sediment matrix, and therefore, we cannot know if these were transported artifacts or if they were manufactured locally from available small blocks of raw material.

At the same time, the layers that folded during the last uplift of the Kendeng hills have yielded some poor quality limestone artifacts as well as fossils at Miri (Kedung Cumpleng site) in an alluvial delta environment. This reflects the milieu of life for hominids on reliefs emerged at the end of the Lower Pleistocene, not long before the central region of Java acquired its current tectonic configuration.

The Beginning of the Middle Pleistocene in Java

The settling of climatic conditions that characterizes the Middle Pleistocene, from the isotopic stage MIS 22 for the earliest, marked a major stage in the paleobiogeographic evolution of the region and correlatively in the history of its peopling. It is in fact during this period that the largest land bridges on the Sunda plateau were exposed, the nature of fauna evidencing important exchanges between the continent and the archipelagos. Accordingly, the dispersion of hominids has thus been facilitated by:

- The opening of the landscape, generally considered as favorable to the development of human groups.
- But also the balance which was established in the geographic configuration of the Sunda shelf. Waters flowing from the emerged massifs (Java, Sumatra, Borneo) joined and structured the corridors along important rivers, bordered by gallery forests providing to the shifting humans vital resources, catering for their subsistence and technical needs.

Many deposits within the Sangiran dome yielded in situ or very slightly reworked archaeological horizons, such as the site of Ngebung (Fig. 5). Others (Pucung, Grogolan Kulon (Fig. 6)) derive from the direct destruction of archaeological soils and thus enable, particularly in the case of Pucung, a representative and qualitative approach of these despite a disturbed spatial distribution. Worth noting in these horizons is the simultaneous occurrence of faunal remains showing traces of human activity, sometimes the remains of the hominids themselves, traces of plant elements (bamboo casts in clay formations), and stone tools.

They are included in the layers known as of Kabuh – or Bapang – whose age corresponds to the very beginning of the Middle Pleistocene.

Some dating of volcanic effluents such as pumice gives a more remote age (Lower Pleistocene), but the primary character of the dated elements remains subject to debate. Efforts to date the sites thus combine several approaches: comparative dating methods by potassium argon on pumices but also on potassium-rich mineral grains collected from tuffaceous layers contemporary to eruptions, dating by electron spin resonance (ESR) of bipyramidal quartz of volcanic origin,

Insular Southeast Asia in the Lower Paleolithic, Fig. 5 Ngebung site (Sangiran dome, Java, 800 ka). (**a**) Excavation, (**b**) flake on chalcedony, (**c**) bola, (**d**) cleaver in andesite, (**e**) probably utilized Stegodon tusk large flake, (**f**) Axis lydekkeri ngebungensis (Cervidae), (**g**) bovid mandible (© Centre archéologique national d'Indonésie et Muséum national d'histoire naturelle)

and dating by combined uranium series (U/Th) and ESR on tooth enamel of large herbivores.

Lithic tools are represented by "Sangiran flakes" (including small cores and retouched pieces) on allochthonous rocks, with different degrees of patina and wear (from very fresh to very rolled). This observation, made in the 1990s, and confirmed by the discoveries of Dayu mentioned above, closed the debate on the age of the "Sangiran flakes" as defined by von Koenigswald, whose dating was often questioned in the literature: these fragments, regardless of their geographic origin, are indeed the work of *Homo erectus*.

Extensive use was made of rocks available nearby; at Ngebung there appear numerous pebbles of andesite of poor quality, probably collected from the river levels eroding the lahars. These pebbles were used for some of them as simple manuports, for others trimmed by knapping into "horsehoofs" or shaped along a chain of operations whose products ranging from polyhedrons to the perfect bolas (Fig. 5c) through more or less regular spheroids.

In the 1970s, R.P. Soejono discovered, in a test pit excavation in Ngebung, a chopper on metamorphic rock. The group of sites known today regularly yields artifacts in quartz, quartzite, and hard fine-grained andesite which were made on blocks whose size sharply contrasts with the granulometric size of the surrounding deposits in the Kabuh layers. The location of the outcrops provides a good idea of the extent of the territories in which the raw material was harvested, whose radius could probably be up to 25 km.

Insular Southeast Asia in the Lower Paleolithic, Fig. 6 Grogolan Kulon site (Sangiran dome, Java, Early Middle Pleistocene). (**a**) Large flake, (**b**) polyhedron quartzite, (**c**) pebble tool (Photographs by Truman Simanjuntak)

These imported materials were used as hammers and as supports in making choppers and chopping tools or bolas (sometimes not pecked, notably on fine-grained quartzite). But we also find sharp tools like cleavers on large flakes (including a large Kombewa-type flake). In Ngebung, a large flake in proboscidian ivory (Fig. 5e) was also found (Sémah et al. 1992).

Behavioral differences appear between the sites, which remain to be analyzed with more precision, such as the average mass of bolas, which varies by assemblage between 350 and more than 800 g, or the raw materials used to make them.

These are key sites. They are the oldest which offer a new insight, unknown up until the end of the twentieth century, on the lifestyle of the "Pithecanthropus" of Java, their subsistence and technical behaviors (hunting seems certain), and the extension of their territories. Similarly, it is important to mention a recent study on the

ancient collection made by Eugène Dubois in Trinil, which shows the high probability of exploitation of aquatic resources (notably mollusks) by *Homo erectus* from the end of the Lower Pleistocene.

Diffusion of the Acheulean Toward the Archipelagos

The recurrence of lithic pieces described above, in excavations undertaken in Sangiran, appears today to indicate diffusion toward the archipelagos of the Acheulean tradition at the dawn of the Middle Pleistocene. While the presence of bifaces is substantiated in East Asia (China and Korea), reference points are still lacking between the Acheulean sites of India such as Attirampakkam (around 1.5 Ma) and the Southeast Asian archipelagos. The few discoveries made in northern Thailand remain contested from a chronological point of view and hardly distinctive from a typological perspective.

The deposits of the Sangiran dome raise the question of the distribution of the "Large Flake Acheulean" (Mishra et al. 2010) and imply addressing anew a number of discoveries made in alluvial environments (and still poorly dated) such as tools on large flakes and bifacial pieces found within the Patjitanian industry in the valley of the Baksoka River in East Java. Several distinctive pieces (hand axe, cleaver on flake) were also mentioned in South Sumatra (Fig. 2a/b), in the alluvia of tributaries of the Ogan River (karst massif of Baturaja).

This perspective can also be taken beyond the Wallace Line, from the Walanae River terraces in Sulawesi (Cabengian assemblage) all the way to the Soa Basin in Flores (Fig. 2a/a), where in 1970 Theodor Verhoeven drew attention to shaped pieces associated with ancient fauna (assumed to belong to the Middle Pleistocene).

Von Koenigswald quickly brought them together with the "Sangiran flakes." The intensification of research in the Soa Basin allowed for the identification of several sites (Mata Menge, Boa Lesa, Wolo Sege) dated between 0.8 and 1 Ma by argon methods and fission tracks (Brumm et al. 2010).

The tools collected include, besides pebbles, mainly medium-sized flakes resulting from the reduction of blocks, and are easily transportable from where they were produced with the possibility of being retouched thereafter.

A comparable behavior was noted in the horizons where the *Homo floresiensis* fossil was discovered (Liang Bua, Upper Pleistocene), which allowed the authors to assume some continuity in acquisition strategies and the treatment of raw materials in Flores throughout the Middle and Upper Pleistocene (this hypothesis supports that of a long endemic evolution on the island).

In the Philippines, the Kalinga site in North Luzon attests overseas dispersal of hominins in the early Middle Pleistocene around 700 ka. The lithic assemblage associated with numerous faunal remains only comprises small flakes (Ingicco et al. 2018). Other assemblages still lack chronological data especially the unifacial pebbles of Cagayan (Cabalwanian, north of Luzon island (Fig. 4a, b)), the "Acheulean" pieces from the Arubo site (central part of the island, biface and "horsehoof" (Fig. 3a), and the pebble tools of Huluga (Cagayan de Oro, north of Mindanao island (Fig. 4c–e)) (Dizon and Pawlik 2010).

The data collected, notably in Flores, implies that *Homo erectus*, during the establishment of the specific paleogeographical conditions of the Middle Pleistocene, was also able to cross the narrow channels of sea in order to populate the eastern islands. Many speculations accompany this assertion, such as the visibility of reliefs (volcanoes) which could have represented an incitement to cross. This adventure seems surprising if we refer to the reliability of the Wallace Line considered as a biogeographic boundary. However, it is no more spectacular than what the first *Homo erectus* experienced about 1.5 Ma ago, as they successfully passed the filters separating the continent from the first hospitable reliefs appearing on Java.

The Industries at the End of the Middle Pleistocene

The sites from the Lenggong Valley in Peninsular Malaysia (Majid 2001), recently classified on the

World Heritage List, represent a potential link with the abovementioned sites. In Bukit Jawa, during the construction of a highway, the identification of a workshop became the object of rescue excavations on the periphery of a relief formerly surrounded by a lake. It yielded a very high number of artifacts on pebbles and large flakes, often knapped on an anvil, and its age could be as old as 200 ka. The Kota Tampan site, where stone knapping workshops were also excavated, occupies a comparable geomorphological position and presents a more sophisticated lithic industry but involving comparable reduction methods.

Made by knapping on an anvil or by direct percussion, the tools on pebbles or flakes (mainly notches and denticulates) show the use of quartz but also the search for good quality quartzite. The overlying layers at some archaeological horizons were dated (luminescence, OSL) to more than 70 ka, linking the abandonment of the site with the major eruption of the Toba volcano in North Sumatra (Fig. 2a/b). The Lenggong Valley also contains many other sites that are more recent.

Several other lithic assemblages on flakes were discovered in alluvial systems of east and west Indonesia and are attributed to the Middle or Upper Pleistocene. The majority, however, lack precise stratigraphic and chronological context, owing as much to the rarity of research as to the difficulty of finding well-defined stratigraphic horizons in highly dissected alluvial layers, most often reduced to the state of geomorphologic berms. In particular, mention must be made of the presence of some knapped pieces, including a chopper on a large andesite flake, on the site where the Sambungmacan skullcap was discovered in 1973, belonging to the late *Homo erectus* group from the Solo River. In the karst massif of Punung (east of Java island), the Song Terus cave (Fig. 7) was the object of a study on its deep filling which demonstrated an old opening onto the neighboring valley. The filling of the cave thus trapped alluvial layers which contained abundant artifacts and some fossils (Sémah et al. 2004). This alluvial series could be dated back to more than 300 ka (dating combining U/Th and ESR methods) in its deepest area. It ends with isotopic stage MIS 5 (the U/Th speleothem dates are between 120 and 85 ka), with the disappearance of all fluvial influence and the outlining of the oldest occupied surface in the cave known in the region studied, toward 85 ka.

The lithic industry associated with these deep levels is homogenous throughout the entire period. It is characterized by the opportunistic production of flakes of medium or small size, an important proportion of which (including cortical flakes) was retouched. The tools include typically denticulated scrapers, as well as notches, becs, scrapers, and borers. Composite tools are common. Tools on pebbles, cores, or large flakes are rare, probably because of the limited granulometric size of the encasing alluvial layer.

Homo sapiens of the First Part of the Upper Pleistocene

These sites open up perspectives on the period during which *Homo sapiens* conquered the archipelagos, but the association between technocomplexes and human fossils remains too tenuous to be able today to claim a detailed description of the behavior of the first representatives of our species. Some continuity reflected by lithic technology appears notable but still requires interpretation. Such is the case of the karst of Punung in East Java (until the end of MIS 5), where it is difficult to attribute the very first occupation floor in the cave to the last *Homo erectus* or to the early arrival of *Homo sapiens*.

Similarly, in the valley of Lenggong in Peninsular Malaysia, where, as mentioned above for Flores, continuity in lithic reduction modes could well have been dictated by nature and the locations of raw material sources. One of the characteristics of these tools in the region of Punung, from the end of the Middle Pleistocene until the Holocene, is the frequent recycling of older artifacts, either by resharpening or their use as cores.

Diversification seems to be more evident at the end of MIS 3 and during MIS 2, possibly linked to the ease of circulation on the emerged corridors,

Insular Southeast Asia in the Lower Paleolithic, Fig. 7 Song Terus cave (Punung, Pacitan, Java, Indonesia). Human presence for more than 300 ka; occupation floors from 85 ka. (**a**) Excavation, (**b**) tool on bone (Holocene), (**c**) tool on shell (Holocene), (**d**) core (Holocene), (**e**, **f**) retouched flakes of the Terus level (Late Middle Pleistocene) (© Centre archéologique national d'Indonésie et Muséum national d'histoire naturelle)

crossing of the narrow straits toward the eastern islands, and the variety of tropical ecosystems which humans began exploring and exploiting.

The data accumulated during recent decades are still scattered but contribute to stressing the importance of research efforts in the field, combining archaeology and chronology. They clarify diverse aspects relative to the movement and adaptation of modern humans in the archipelagos, such as the specific exploitation of environments in Sarawak (island of Borneo, Niah Cave; Barker et al. 2011), the apparent occasional use of caves as short-term shelters and, more rarely, workshops in the karst massif of Punung in Java (Forestier 2000). They also highlight the diversity of human species in this time period including not only *Homo sapiens* and *H. floresiensis* but also *H. luzonensis* from Callao Cave (Fig. 2a/c) to the north of Luzon island (around 67 ka ago; Detroit et al. 2019). It is worth mentioning the likely presence of a Levallois reduction in South Sulawesi (Maros karst (Fig. 1), Leang Burung 2; Glover 1981); the occupation of the Tabon Caves (Palawan Island (Figs. 2a/c and 8)) nearly 35 ka ago, as hearths and associated flake assemblages (Patole-Edoumba et al. 2012); the traces left by the first navigators passing through the Moluccas archipelago (caves of Golo and Wetef on the island of Gebe; Bellwood et al. 1998); or in East Timor (Jerimalai shelter, O'Connor et al. 2011 (Fig. 1)), where the oldest traces of deep sea fishing can be found.

International Perspectives

The ideas expressed by Movius on the regions situated beyond the "hand axe limit" seem obsolete today. However, it is undeniable that the perspective that it opened during the 1940s on early prehistory of Eurasia led to genuine incentives for the development of research (Simanjuntak et al. 2010).

A "continental" point of view continues to guide some work, notably research into the mechanisms of diffusion and local specialization of the Acheulean tradition, as well as research for older evidence of systematic fire use. But it seems difficult today to follow Movius's idea in his perception of the whole region under study as a simple isolate or even as an evolutionary cul-de-sac.

On the contrary, the chronological and geographic mosaic of settlements in the Southeast Asian islands during the Pleistocene has already confirmed its potential. The region contains some of the earliest evidence of adaptation to tropical, continental, and aquatic environments and their exploitation during the Lower Pleistocene. At the dawn of the Middle Pleistocene, clearly, the question of the modalities used to cross the straits, resulting in the installation of groups on the Lesser Sunda Islands, begs an answer. The second half and end of the Upper Pleistocene are rich in innovations which would contribute to the debate of "cultural modernity". As, for instance, the organized navigation, these innovations concern the understanding and mastery of a number of natural processes (Bellwood 2007). They enabled the colonization of new lands and a targeted exploitation of their resources, prefiguring in many cases the domestication of the environment.

Future Orientations

The practical orientations for research are modeled on the statement of the potential of sites, which has been summarized here.

The question of technical behavior and subsistence of the oldest *Homo erectus* which populated the archipelagos involves going through the same approach for formations such as the deposits of Pucangan in Sangiran as that which could have taken place within the volcano-fluviatile layers of the end of the Lower Pleistocene. The first direction to follow is certainly that of paleontology and taphonomy in order to obtain a real view of the content and the mechanisms for the deposition of the richest fossil-bearing strata.

The second perspective concerns the entire documented archaeological record from the beginning of the Middle Pleistocene to the beginning of the Holocene. The natural tendency, as a result of the small number of studies and their dispersion, is always to give a particular meaning to a determined point in space/time, especially in

Insular Southeast Asia in the Lower Paleolithic, Fig. 8 Tabon cave (Lipuun Point, Palawan, Philippines). (**a**) Lipuun point, (**b**) excavation, (**c**) flake tools (according to Fox 1970) (© Eusebio Dizon – National Museum of the Philippines)

terms of adaptation to very local conditions. Testing the solidity of such preliminary models requires a multiplication of quasi-synchronous markers in the same region, the careful description of the differences in context between them, and an attempt to find the constants in terms of adaptation or cultural choices (Simanjuntak et al. in press).

Taking into consideration international perspectives, these future orientations must also enable, at the level of the whole region, the implementation of a common policy of conservation and interpretation, which could easily take the form of thematic nomination (and not of isolated sites) to the World Heritage List. Such an appreciation of prehistoric heritage will go beyond its

scientific interest. As a true narration of entire chapters of human history, it will echo the discourse, very often ancestral, which local communities have developed in order to substantiate deep cultural roots in their territories.

Intangible Cultural Heritage

Gail Higginbottom
School of Archaeology and Anthropology, The Australian National University College of Arts and Social Sciences, Canberra, Australia

Introduction and Definition

In its most literal form, intangible cultural heritage (ICH) can be defined as heritage that has no material form, such as a belief system transferred through word of mouth, like a song of creation or a language without written form. However, the destruction of tangible heritage physical can have an effect on these more ephemeral heritages (for instance, landscape cues used in the singing about the creation of the land, local mountains, and river bends) and leaves the stories more open to dispute. In such ways the intangible is directly connected to the tangible.

The emergence and relevance of ICH is linked to philosophical traditions such as those of Bourdieu, Heidegger, and Merleau-Ponty that eventually found their way into archaeology and anthropology in the twentieth century. This more holistic approach toward cultural heritage and its management grew out of the *interpretative tradition*. Specifically, the part is understood within the whole from which it originated, and the whole is understood from the part in which it finds expression (Droysen 1977: 35 in Johnson & Olsen 1992: 421). Such approaches led to questioning the unnecessary division between nature and culture. In the same way, the tangible in heritage cannot be understood without the intangible, for they are all part of the larger system of human experience which is heritage.

Key Issues/Current Debates/Future Directions/Examples

There are many useful papers tracking the history of the adoption of ICH from different angles within UNESCO (including Aikawa 2004 and Munjeri 2004) and from without (Francioni 2004; Ahmad 2006). These also discuss the different aspects of the final UNESCO convention on ICH. This entry will focus on how ICH came into the consciousness of the modern international political arena, as highlighted by these and other papers.

In 1971, UNESCO drafted its first international instrument related to ICH (document B/EC/IX/II-IGC/XR.I/15). It aimed at establishing the protection of folklore (Aikawa 2004: 138). Francioni (2004: 2–3) showed that the international legal interest in such protection actually stemmed from World War I and became more fully manifested after World War II. In 1948, the United Nations (UN) *Universal Declaration of Human Rights* upheld that "the concept of human dignity":

> includes peoples' entitlement to the respect of the cultural heritage that forms an integral part of their identity, history and civilization. Destruction or desecration of *symbolic* objects and sites that *are essential to the enactment of a people's culture* (Francioni 2004: 4; fn 7,8,9 for full referencing of this declaration).

Importantly, the above statement affirms the relevance and importance of intangible and tangible values and behaviors for humanity as a collective as well as its deconstructed cultural parts. Thus, *all* people and their cultural *behaviors* and *places* matter. Significantly, *living* aspects of culture matter, not only those that were created in the past and bestowed to us by our forebears. Such agreements have "provided the foundation for the gradual building up of a movement toward the recognition of a distinct and enhanced status of indigenous peoples" (Francioni 2004: 3).

From 1971 on, several years of debate ensued on how to protect ICH either through a separate normative instrument or via Intellectual Property Rights (Francioni 2004: 15; Aikawa 2004: 138). In 1989, the Recommendation on the Safeguarding of Traditional Culture and Folk Law was published. Unfortunately it was not binding and UNESCO and others struggled with how to define ICH, what kinds of things should/could be protected,

and how to create explanations of how to protect what (Francioni 2004: 15–6; Aikawa 2004: 139–41).

From 1990 on, many other influences were brought to bear on the creation of a more holistic CHM identity and strategy. *The United Nations Convention on Biological Biodiversity* (1992) was responsible for highlighting the significance of ICH further through emphasizing the significance of traditional, indigenous knowledge and practices upon the conservation and sustained use of biodiversity. This, along with The United Nations Draft Declaration on the Rights of Indigenous Peoples, had two major effects. They were catalysts of winning support for the recognition of the ICH of indigenous peoples and highlighted the significance and relevance of cultural diversity and the engagement of "the many" in decision making.

In the years up to 1998, as well as in the same year, intergovernment meetings were debating the notion of heritage and the limitations of seeing it as synonymous with the tangible. The *Intergovernmental Conference on the Cultural Policies for Development* (Stockholm, 30th March–2nd April, 2008, P16 Recommendation Objective 3.3) recommended that states renew "the traditional form of heritage", namely that which "must be understood as all natural and cultural elements, tangible versus intangible, which are inherited or new." This is/was seen as indigenous peoples' holistic conception of heritage.

Cultural diversity and engagement of "the many" are social forms of "plurality," the significance of which has been much debated in political/social philosophy. Plurality in these forms is now seen as a fundamental working principle for environmental health globally (biodiversity) as well as for the notion of cultural heritage (cultural diversity) and its management. In 2001, UNESCO adopted the *Universal Declaration on Cultural Diversity*. This provided strength of argument that the future of cultural heritage can only be decided by many voices and is seen as pivotal to humanity's survival and strength as a whole.

Despite these constant "reawakenings," progress was generally slow through the second half of the twentieth century. This can be seen as a result of a very fundamental social phenomenon in itself. European and other highly urbanized societies' ideologies changed in the mid-twentieth century to the mid-1980s. It was during this time that processual philosophy was strong (understanding society as a series of processes) and science and the tangible held sway. Things could not be "true" or confirmed if they were not material, so perhaps we could only be certain about material heritage. It was during the 1980s that a large number of individuals began to debate the dominance of the positivist view of the world (post-processual) and things that were physically created by people as opposed to the "natural" in CHM and archaeology.

Linked to these ideas, Munjeri points out that CH practitioners, thinkers, and the public tended to see CH as a stable and static "authentic" entity (2004: 13). Heritage was qualified and reduced to "types" where authenticity was identified only through physical qualities like its "authenticity of materials" or design. Such value judgments place these forms of heritage into the past and associate their past visible value with the current visible value.

To further understand how it took so long for these ideas to become a central UNESCO canon during these times requires a solid study of the documentation that came out of the various UNESCO and other international meetings. This is recommended for those readers who wish to understand in what ways the representatives of various countries saw and understood things differently from each other, including the importance of the protection of ICH. Many of these differences are retained today. So altogether, lack of recognition, political and philosophical wrangling and issues surrounding authenticity, slowed the progress of the understanding, adoption and use of the intangible in heritage. Regardless, the

Operational Guidelines for the Implementation of the World Heritage Convention have progressively encompassed intangible aspects embodied in natural and cultural sites.

In the late twentieth century, works appeared that emphasized the place and importance of nature and/or critiqued those traditions that have devalued it or felt that its "form" has been misunderstood (Vogel 1996). Further, the understanding of the notion of special places as non-physical entities (being special due to the practices that were held there), and the acknowledgement of the significance of living cultures as part of the heritage of humanity, led away from "European" ideologies of grandiose structures and concentration on the past (Munjeri 2004: 14–16). In the last 20 years, some CH specialists see ICH as enveloping the tangible or indeed that the tangible is the physical manifestation of the intangible. Others describe it as the framework within which the tangible takes shape and significance. Munjeri upholds that heritage is a tripartite whole that he calls the equilateral triangle of natural, cultural, and spiritual and that these are parts of the greater whole in which ICH is enmeshed.

In a world debating ideas like these, several countries requested UNESCO to develop a *new international normative instrument related to ICH*. In 1999, the *Global Assessment of the 1989 Recommendation* revisited the 1989 instrument and examined the efficacy of its application among Member States (MS). By 2003, the MS found enough common ground to adopt an *International Convention for the Safeguarding of the Intangible Cultural Heritage*. This document contains the current definition of ICH by UNESCO (article 2):

> The "intangible cultural heritage" means the practices, representations, expressions, knowledge, skills – as well as the instruments, objects, artefacts and cultural spaces associated therewith – that communities, groups and, in some cases, individuals recognize as part of their cultural heritage. This intangible cultural heritage, transmitted from generation to generation, is constantly recreated by communities and groups in response to their environment, their interaction with nature and their history, and provides them with a sense of identity and continuity, thus promoting respect for cultural diversity and human creativity. For the purposes of this Convention, consideration will be given solely to such intangible cultural heritage as is compatible with existing international human rights instruments, as well as with the requirements of mutual respect among communities, groups and individuals, and of sustainable development (UNESCO 2003).

Intellectual Property Issues in Cultural Heritage (IPinCH) Project

George P. Nicholas
Department of Archaeology, Simon Fraser University, Burnaby, BC, Canada

Basic Information

Description

The Intellectual Property Issues in Cultural Heritage (IPinCH) project (2008–2016) was an international, multidisciplinary research project examining intellectual property (IP)-related issues emerging within the realm of heritage, especially those affecting Indigenous peoples (Fig. 1). These include complex and often difficult questions about who has rights to and responsibilities relating to use of and benefits from tangible and intangible cultural heritage, including artifacts, archaeological sites, and associated traditional knowledge (e.g., images, songs, stories) and values (Nicholas and Bannister 2004). To address these issues, IPinCH was designed to assist scholars, institutions, descendant communities, policymakers, and other stakeholders in negotiating equitable, appropriate, and successful research policies and practices involving cultural heritage, including archaeology. The project also generated insights on the nature of knowledge, extending understanding of IP and contributing to scholarly discussions of culture-based rights claims.

Intellectual Property Issues in Cultural Heritage (IPinCH) Project, Fig. 1 The IPinCH logo, "Perpetuation", was designed by lessLIE (Leslie Sam), a Coast Salish artist who works at the interface of traditional and modern values, modes of expression, and social and political inequities (The image is used with the permission of the artist who was an IPinCH affiliate)

IPinCH was a collaboration among scholars, researchers, and Indigenous groups from across the globe. Team members from diverse fields – including anthropology, archaeology, ethics, ethnobiology, Indigenous studies, heritage management, information management, law, and museum studies – worked with professional and community practitioners and policymakers from agencies and institutions operating at local, national, and international levels. A critical aspect of the project was the involvement of Indigenous partners and organizations from Canada, the United States,

Australia, New Zealand, South Africa, Botswana, Japan, and Kyrgyzstan. The project was based at Simon Fraser University (Canada), with George Nicholas as project director.

The conception of IPinCH emerged from discussions in the early 2000s between archaeologist Nicholas, cultural anthropologist Julie Hollowell, and ethnobiologist Kelly Bannister and was influenced by Michael Brown's article "Can Culture Be Copyrighted" (1998) and Catherine Bell's Project for the Repatriation of First Nation Heritage in Canada (2000–2009) (Bell and Napoleon 2008; Bell and Paterson 2009), as well as by conversations with colleagues who were encountering intangible heritage-related issues in their work. An 8-year $2.5 million grant was awarded by the Social Sciences and Humanities Research Council of Canada to support the project from 2008 to 2016 as part of its Major Collaborative Research Initiative program.

Project Organization and Research Methodology

At the core of the project was a steering committee composed of Nicholas, Hollowell, Bannister, legal scholar Catherine Bell, and archaeologists Joe Watkins and John Welch, which provided direction and oversight, assisted closely by a student representative and project staff. A grounded critical theory orientation aimed for ongoing evaluation of the projects by naiveness to the varied needs of team members and partners and to changing circumstances affecting the research environment. A project ethnographer provided feedback on communication and knowledge flows within the project to aid IPinCH in meeting its goals and setting priorities. Guidance at the broader level was provided by an international project advisory board. Communication and outreach tools include a still-active project website (www.sfu.ca/ipinch), newsletters, monthly digest, and variety of social media for sharing news within the project and with the broader public. Over the course of the project, the team grew through the addition of 140 associate members and affiliated students.

Addressing Community Heritage Needs at Ground Level

Twelve IPinCH-funded *community-based initiatives* (Table 1) were situated within Indigenous communities around the world (Hollowell and Nicholas 2009). Each project was co-developed with community partners who are fully involved in developing research questions, methods, and outputs and reviewing project data before being made public. These community-based initiatives targeted a wide range of issues, including developing protocols to work with ancestral remains (Schape et al. 2015), educational programs (Abdykanova et al. 2016), integrating traditional cultural principles and ways of knowing in local management decisions and government consultations (Carcross-Tagish First Nation et al. 2016), developing means to repatriate and restore to community knowledge from materials in museum collections (Arnold 2014), and creating co-management plans with state agencies to protect the intangible values of culturally significant places (Atalay et al. 2016).

In general, these initiatives were self-sustainable, culturally appropriate, and community-embedded projects that addressed the preservation and educational use of IP and cultural heritage. In a number of these projects, elders and youth worked together to collect, inventory, and preserve traditional knowledge (e.g., Thorpe and Solomon 2014). Other projects were undertaken in collaboration with the Ainu of Northern Japan (on conceptions of heritage), the Tlingit and Haida of the Pacific Northwest (on precontact resource harvesting), and the San of Southern Africa (on cultural tourism).

What these projects revealed includes:

- On-the-ground studies reveal different conceptions of "heritage," "property," and what constitutes proper care, as well as responsibilities to and relationships with "heritage."
- Repatriation of heritage is not limited to material items but also information and knowledge.
- The need/demand for Indigenous-based heritage models is substantial and urgent.

Intellectual Property Issues in Cultural Heritage (IPinCH) Project, Table 1 IPinCH-funded community initiatives

"A Case of Access: Inuvialuit Engagement with the Smithsonian's MacFarlane Collection" (Northwest Territories, Canada) – Repatriation and restoration to community of knowledge from museum collections
"Education, Protection and Management of *ezhibii-gaadek asin* (Sanilac Petroglyph Site)" (Michigan, USA) – Co-management of petroglyphs and their intangible values
"Cultural Tourism in Nunavik" (Québec, Canada) – Protection of Inuit language and heritage in the context of cultural tourism
"Developing Policies and Protocols for the Culturally Sensitive Intellectual Properties of the Penobscot Nation" (Maine, USA) – Long-range stewardship plan and research protocols for tribal intellectual property
"Grassroots Heritage Resource Preservation and Management in Kyrgyzstan:" (Kyrgyzstan) – Developing sustainable community projects that preserve and teach about intellectual property and cultural heritage
"Hokotehi Moriori Trust: Heritage Landscape Data Base" (Rehoku, New Zealand) – Database of traditional knowledge of cultural landscape that brings together elders and youth
"Secwepemc Territorial Authority – Honoring Ownership of Tangible/Intangible Culture" (British Columbia, Canada) – Exploring "cultural heritage" when Secwepemc peoples have economic, political, and legal authority
"The Journey Home – Guiding Intangible Knowledge Production in the Analysis of Ancestral Remains" (British Columbia, Canada) – Developing protocols for acceptable methods of study of ancestral remains before reburial
"The Ngaut Ngaut Interpretive Project" (South Australia) – Development of culturally sustainable interpretive content online for important heritage site through a community-based approach to interpretive materials
"Treaty Relations as a Method of Resolving IP Issues" (Canada) – Using the nineteenth-century treaties as a framework for resolution of outstanding intellectual property and heritage issues today
"Yukon First Nations Heritage Values and Heritage Resource Management" (Yukon, Canada) – Identifying local conceptions of heritage values in aid of self-governing Yukon First Nations' management of their heritage resources
"The History and Contemporary Practices of the Hopi Cultural Preservation Office" (Arizona, USA) – An examination of the Hopi Tribe's navigation between radically different conceptualizations of Hopi cultural knowledge and those informing Euro-American interests

- A different research process is needed in which direction comes from heritage holders.
- Community-based research requires developing mutual understanding of needs, goals, methods, and outcomes, as well as trust and respect.
- University policies generally foreground researcher's interests over the community's and that university ethics review criteria and policies must adjust to new needs.
- Cross-cultural differences matter.

Research Themes During the lifetime of the project, IPinCH maintained seven topical working groups, from which these primary research themes were drawn: (1) Bioarchaeology, DNA, and Indigeneity; (2) Commodifications of Cultural Heritage; (3) Community-Based Cultural Heritage Research; (4) Cultural Tourism; (5) Indigenous Peoples, Cultural Heritage, and the Law; (6) Indigenous Research Ethics; and (7) Safeguarding Indigenous Heritage. Working group research was innovative and collaborative, involving scholars, students, and research partners from around the world to explore the topics listed relative to theory, practice, policy, and research on IP issues in cultural heritage.

Research efforts and output relating to these themes took a variety of forms, depending upon whether they were directed to academics and researchers, Indigenous and other descendant communities, policymakers, or the public at large. There was extensive academic output and conference sessions, along with a public lecture series on "Protecting Indigenous Cultural Heritage," and combined workshops/public symposia on "Cultural Commodification, Indigenous Peoples, and Self-Determination" and "DNA and Indigeneity: The Changing Role of Genetics in Indigenous Rights, Tribal Belonging, and Repatriation" (see Walker et al. 2016). IPinCH also produced an array of Fact Sheets and blogs, >100 videos and podcasts, newsletters, conference proceedings, and reports on the community-based initiatives. All are available on the IPinCH website.

Major Impact

The IPinCH project was an unconventional academic research project that sought a more complete understanding of the complex IP issues that increasingly affect Indigenous knowledge systems and research relationships. It offered assistance and resources to diverse stakeholders to better understand and address these concerns.

The project also helped to build capacity both within communities and in the academy. Approximately one quarter of the IPinCH project budget was committed to student support and training. Research fellowships supported graduate students and postdoctoral scholars in investigating specific IP issues. Students, scholars, and others interested in these issues had the opportunity to become IPinCH associates and participate in working groups and other project initiatives and events.

The insights gained through collaborative projects developed with Indigenous partners have helped to catalyze new theoretical insights, policy development, and more accountable research relationships. These promote better understanding in both the nature of Indigenous intellectual property and notions of heritage in which tangible/intangible "property" is indivisible. This research also revealed substantial challenges in funding community-based studies through conventional academic channels that foreground university interests, with considerable time and effort directed to implement ethics reviews and grant transfers and to ensure that community partners retained ownership and full control of research results.

Knowledge mobilization and activism were important components of IPinCH. For example, in 2014 IPinCH team members developed the *Declaration on the Safeguarding of Indigenous Ancestral Burial Grounds as Sacred Sites and Cultural Landscapes* (https://www.sfu.ca/ipinch/resources/declarations/ancestral-burial-grounds/) as an intervention in the desecration of an ancestral First Nations burial ground in British Columbia. This document articulated the growing global consensus around the importance of protecting Indigenous ancestral burial sites and called on all levels of government, heritage professionals, and others to work together to ensure such sites are not subject to alteration or damage. It served to remind non-Indigenous governments in Canada of their legal and ethical obligations with respect to First Nations' sacred sites in which human remains of cultural and spiritual significance are interred. The Declaration received endorsements from leading professional organizations around the world, as well as a large number of scholars and private citizens, and is thought to have had a significant influence on encouraging the BC government to resolve the situation.

IPinCH was itself a case study in alternative research ethics and practice. Shifting control over the research process to community partners revealed significant tensions between the project, university policies, and funding agencies. Some of the IPinCH-supported projects literally took years to have funding and ethics applications approved, pointing to the need for revised university policy. To aid that process, and to share lessons learned, IPinCH hosted a national research ethics conference, "'Working Better Together' Indigenous Research Ethics Conference," which brought together scholars, practitioners, students, administrators, and policymakers of diverse cultural and professional backgrounds from across Canada to explore what it means to work collaboratively in Indigenous research.

In 2013, George Nicholas and IPinCH were awarded Canada's Social Science and Humanities Research Council's inaugural Partnership Impact Award for its outstanding innovative approach to cultural heritage research that encouraged Indigenous community partners to drive the research process and share intellectual leadership and resources.

Since the formal completion of the IPinCH project, many team members continue to pursue related research and outreach on such topics as cultural appropriation, research ethics, human rights, sovereignty-based heritage, and heritage as a human right.

Interculturality and Archaeology

Charles E. Orser Jr.
Department of Anthropology, New York State Museum, Albany, NY, USA

Introduction

Interculturality results when people from different cultures come together in the same place and interact. In a perfect world, the members of diverse cultures would be able to coexist in harmony, learning new ideas and innovative ways of doing things from one another. History has demonstrated, however, that the actual circumstances of cultural contact often result in conflict and control as one culture (typically the more technologically sophisticated) seeks to assert domination over cultures they regard as inferior. Archaeologists, especially historical archaeologists who have the advantage of working equally with excavated and textual information, have been adept at examining the details of interculturality by investigating cultural transmission and rejection in terms of moveable (e.g., ceramics, clothing) and immovable (e.g., houses, plazas) material culture.

Definition

On the most basic level, cultures are composed of individuals who share ways of doing things, general religious beliefs (such as monotheism), language (even dialects of the same language), dress, and so forth. Much culture is based on tradition, or "the way things have always been," even though cultures inevitably change through time. Interculturality occurs when groups with different cultural traditions come into direct, sustained contact. As members of distinct cultures, the various individuals can constructively interact for the betterment of all or they can come into conflict.

Constructive interculturality might be termed "positive interculturality." Regrettably, however, interculturality has been difficult to effect when one of the cultures in contact perceives itself as more powerful, wiser, or divinely unique. Significant problems can arise because of a culture's preconceived ideology of superiority. Many of the beliefs about superiority/inferiority are based on what most people refer to as "race." Anthropologists determined long ago that race does not exist as a biological fact. Rather, peoples in different genetic populations share the same physical attributes because of the complex interactions between genetics, environment, and climatic conditions. Nonetheless, people tend to believe that they perceive distinct human "races" because of the racialization process, and so the process has played a historical major role in making positive interculturality difficult to put into practice in many situations. The racialization process constitutes an element of what might be termed "negative interculturality."

Examples

The racialization process has made interculturality difficult to sustain in living populations, particularly during the nineteenth-century diasporas that took millions of immigrants to the United States. The unfair conditions the immigrants faced, however, does not mean that they did not coexist with other immigrants and learn from them despite the cultural differences between them. In this sense, positive and negative interculturality can occur side by side in any social environment in the same way that

views about interculturality can exist through time as cultural tradition.

Interculturality marked the late nineteenth-century history of New York City, for example, even though the different nationalities (representing distinct cultures) often lived in their own neatly demarcated neighborhoods, worshipped in their own churches (often using native languages in their liturgies), built social organizations designed to protect the neighborhood and to promote ethnic pride, and even created gangs for the purposes of organized crime. Interculturality was constantly practiced in a multicultural place like nineteenth-century New York City. Millions of immigrants entered the city during the nineteenth century, with the largest European in-migration occurring during the last half of the century. The earliest unwilling immigrants, of course, were enslaved men and women who arrived either directly from Africa or from Africa by way of the Caribbean and who were imported as chattel. These individuals labored along the docks, served dinners in elite restaurants, and helped their masters get dressed in the morning. Archaeologists have repeatedly demonstrated the ways in which interculturality was enacted in plantation and urban settings as European American slave owners, overseers, merchants, and artisans learned from African craftspersons, midwives, healers, and cooks. At the same time, individuals of African descent and heritage adopted European languages, housing forms, and religion, even as they may have modified each custom to create new "creolized" cultural expressions that openly proclaimed new social identities. New York City experienced a huge influx of European-born immigrants in the late nineteenth century, first principally from Ireland (as families fled the horrors and deprivation of the Great Famine of 1846–1850) and Germany (as individuals fled the oppression that followed the failed 1848 revolutions). Before the end of the century, so-called "new" immigrants arrived from southern and eastern Europe as well as from other countries that were experiencing difficult economic circumstances or tense political climates. Many people went to the United States simply to find a better way of life, even though the reality seldom fit the dream.

Throughout the nineteenth century, thousands of Chinese and Japanese immigrants also entered the western United States to find labor with mining companies or with the railroads. These immigrants initially settled in large urban centers like San Francisco but steadily moved east, eventually arriving in New York City and other eastern cities. Interculturality during mass migration was made difficult in the United States because of perceived differences between "race" (individuals of African and Asian descent had physical characteristics that were different than those of the upper-class, elite, "white" Brahmins who ruled the nation), religion (Irish, Italians, some Germans, and others professed the Roman Catholic faith rather than the Protestantism of the ruling class), and tradition (Jews, Lithuanians, and others dressed in ways that were perceived as "foreign" to the elite). During this era, elite, well-educated whites created a number of exclusionary organizations formed around the principles of limiting immigration of "foreign undesirables," denying opportunities for advancement to immigrants, and denigrating the Catholic faith. These actions were explicitly designed to implement negative interculturality on a national scale. Their efforts were successful to a point, but positive interculturality nonetheless occurred as different peoples interacted in the course of everyday life in the crowded environment of New York. New York City tenements were important physical sites of interculturality as people from diverse cultures lived tightly packed in adjacent apartments. Tenements were small, poorly ventilated, and badly built, and the residents of the various apartments were collectively forced to use a small number of outdoor privies built in the tiny backyards. Families from diverse parts of the world commonly lived in the same buildings, and given the thin nature of the walls, the members of the various cultures could experience other cultures without perhaps even realizing it. Even though some neighborhoods could be demarcated as "belonging" to Russian Jews, former Irish nationals, or southern Italians, members of each culture could reside in the same tenement. For

example, writing in 1900, one person intimately knowledgeable about the conditions of New York's tenements observed that as many as 70 families could live in a single building.

An important archaeological project focused on New York's tenements was conducted in 1991–1992 by archaeologists from Historic Conservation and Interpretation, Inc. The project was designed to salvage information from the historic Five Points district of lower Manhattan on behalf of the General Services Administration who was overseeing the construction of a new federal courthouse. The archaeologists collected almost one million artifacts from the excavation. Archaeologists working with John Milner Associates, led by Rebecca Yamin, conducted the laboratory research, interpreted the materials, and prepared the seven-volume site report. Historical research conducted in conjunction with the excavation supports the contention that tenements were sites of interculturality. For example, in the one block that was the focus of the project, researchers discovered that Irish immigrants (from almost every part of Ireland), Jews from Czarist Russia and Poland, Italians, and African Americans all lived in the block's tenements during the nineteenth century. The historical records were so rich that the researchers were able to pinpoint the location of different families and even to demonstrate the great amount of transition in the buildings through the years.

Interculturality and Political Action in Undisciplined Archaeology

Alejandro F. Haber
Escuela de Arqueología, Universidad Nacional de Catamarca & Consejo Nacional de Investigaciones Científicas y Técnicas, Catamarca, Argentina

Introduction

Multivocality and Interculturality

Multivocality, as an orientation within postcolonial archaeology, is based upon several key assumptions of multicultural relativism. The call to multivocality often fails to address key underlying problematics rooted within the hegemonic epistemic framework from which archaeological practice is ethically justified as a pluralistic practice. By encouraging practitioners to embrace difference without also necessarily acknowledging the mutually constitutive relationships between frequently unequal partners, this risks producing a form of inclusion that potentially hinders both

the counter-hegemonic vocality of dissident voices and political agency outside of the framework of multiculturalism. In such a way, archaeological practice risks reproducing the very privileged position multivocality attempts to undo, reproducing, in turn, epistemological suppositions about what inclusion necessarily entails. In this entry I intend to dig deeper into the character of the intercultural relationship of archaeological knowledge and disciplinary practice. Focusing upon the conditions of political action resistant to postcolonial intervention and the construction of counter-hegemonic intersubjectivities, I will discuss the mutually constitutive character of thought in the context of work in the Kolla territory of Catamarca, in the northwest of Argentina.

Key Issues/Current Debates

Social and Scientificist Archaeologies

It might seem usual that an archaeologist wonders about the sense of archaeology, particularly about its social sense. What is it useful for, the researcher asks her/himself, eager to find a way to justify her/his science, her/his practice, and her/his life, in terms of utility for the society in which she/he lives. The value of knowledge by itself, of history as teacher of life (*magistra vitae*), and of the archaeological as cultural patrimony and significant identity, the transformation of the past and/or the archaeological in the pursuit of development, or the pure and simple amusement of those who practice it and the curious interest of the public are various. And these values are independent of the reasons, senses, or utilities that archaeologists have elaborated to give their science a place in the present time, as if it did not yet well belong here as a sociocultural artifact. Those more compromised with the present society qualify their science with some very appropriate phrases: social, socially useful, and with social commitment. In my opinion, every justification of *social archaeology* characterized by applying the science to a project of social intervention with an ostensibly altruist goal frequently recapitulates the very colonial logics it seeks to elude, because the interventions into new social contexts works to conceal and ultimately naturalize its own former social relationships. As with s*ocial archaeologies*, also *scientificist archaeologies*, justifying science as a value in itself prey on the denial of the social relationships from which they inevitably emerge, although they do not deform such denial by pretending a commitment to the society with which they were already related by hiding their structural relationships. These scientificist archaeologies produce colonial discourses which, put into projects by other archaeologies or by non-disciplinary agents, end up in joining their political practice to the already mentioned social archaeologies.

Beyond the good or bad intentions of the archaeologist, and beyond more or less explicit or active social commitments, the archaeological project carries the violence of placing in the objects, the archaeological "thing," within the space of metaphysical rupture according to which colonial subjectivity is constituted as hegemonic event in culturally heteroglossic contexts (Haber 1999). That is, archaeology reproduces its basic assumption – object and method – through which the colonial difference in the subjectivity of the archaeologist, but also of the descendants and the public, is taken to the objective world, consolidating a division between knowledge and social relationships (Haber 1999). Colonial difference (Walsh 2006), a power differentiator attendant to the difference in the nature of peoples, is placed within the nature of objects – particularly those objects that signify and mark the nature of peoples. Colonial epistemic violence originally exerted over people is transposed to the world of objects, objectified, naturalized, manipulated, and methodologically modulated.

Colonial/Modern Epistemes and Knowledge/Power

As an example, I transcribe some paragraphs from a 1904 field report by Carlos Bruch, entomologist in La Plata Museum, Argentina, detailing an 1898 archaeological expedition to Hualfín, in the province of Catamarca (Bruch 1904). This is the first text published on the archaeology of Hualfín, later to become an area of choice of Argentine

archaeologists, being in time referred to as the *valle maestro* (master valley) because, due to the seriation of the sepulchers existing there, a historical-cultural sequence was elaborated that was, at its turn, the master sequence then extended to the rest of the Andean provinces in Argentina (González and Cowgill 1975).

Bruch's language is characteristic of the archaeology of the early twentieth century. For instance, descriptions abound and some expressions now considered politically incorrect are not hidden. But behind the appearances, what I find of interest in Bruch's text, as with any early text in general – written when the disciplinary habitus had not yet been institutionalized – is that they show with certain clarity the literary procedures through which objects of knowledge are incorporated into specific semantic networks, which, later, turned into a formalized disciplinary language, survive in more naturalized ways (Haber 1995). That is, in this text there is an antiquated flavor, but that is not what strikes my attention here. What is actually of critical importance, behind the anachronistic language, is the kernel of present discourse: the relationships between objects and agents that exist here are the same ones that exist between knowledge and society in current archaeology. Returning to the report of Bruch, Bruch writes:

> On the 18th January I arrived for the second time in Hualfín. The poplars and the willows, characteristic of Catamarca's towns, form there the fences of vast properties and farms extending both sides of the river; the far-off hills and the Colorado hill showing itself over the fluvial terraces as an immense fortress; everything contributes to give the arid and monotonous landscape a picturesque aspect which the traveler remembers in awe after his visit.
>
> And if you later look at the properties around, you soon discover the ruins and cemeteries, last vestiges of the primitive owners; remains of a numerous tribe: old Hualfines.
>
> Helped by a labourer, my guide and companion during the trip, I started excavation on the following day, the results of which I will mention in the order in which they happened.
>
> Over the small terrace on the right and next to the house of Mr. Leguizamón, there are some ruins of stone walls, next to which I observed various ovals, formed by stone lines of regular size half-buried. Assuming they could be tombs, I excavated the first and I tripped on the surface of a quantity of fragments of clay pots, mixed with rocks and the bones of a skeleton, the skull of which I found 50 cm below the surface. Then I discovered a big clay pot and next to it a well-preserved skeleton.
>
> The sepulcher was 80 cm deep and had been lightly built of a wall of oval-shaped stones marked in the surface by other stones (Fig. I).
>
> The pot (N° 1) is 60 cm tall; its surface is rough, not well polished, made of well-cooked brick-colored clay, with two small rounded and wide hands, and horizontally placed almost in the top third portion. Below the mouth there is a face represented in relief: the strips running irregularly in vertical direction are painted in black. I found an empty pot covered with a lid which must have probably been the bottom part of another very similar to this I described, that is, a *puco* or bowl (Bruch 1904).

Bruch then follows with the rest of his findings, sepulcher by sepulcher, pot by pot. As a sample perhaps this was enough. The description of what Bruch finds in the sepulchers is his way to get to know the past of Hualfín, with an old-fashioned style but a modern epistemic frame: material remains are a means to know the past: a past already gone and which can be known with the study of its "last vestiges," the remains and ruins. These remains and ruins allow Bruch to know, they are here telling him that, in the past, there stood the former populated tribe of the Hualfines, owners of the land of Hualfín. The relationship of the Hualfines with Hualfín, which Bruch enunciates as that of past inhabitation and ownership, turns out to be analogous to another such relationship, the one Bruch sees from the top of a hill, and which is signaled by the rows of poplars and willows, limits of the properties in Hualfín when Bruch conducts his field research. Two social relationships happen one after the other in time, although Bruch does not tell us how or why. A succession in time does not mean anything but the time passing; there is nothing to indicate the influence linking Bruch with the Hualfín, and there is no relationship of knowledge articulated, no matter the social relationships with the owners and between them. Let us observe the end of Bruch's text:

> In order to grasp at least a tiny graphic idea of the Quechua population inhabiting the Calchaqui regions today, a population which can be considered descendants of that civilized nation, we

represent, in picture IV, two sketches which I had occasion to draw in Hualfín, in the house of Mr. Leguizamón.

Number 1 is a well-developed thirteen-year-old girl. The head is pretty big and round, the hair is black and stiff, irregularly cut and extending long through the forehead, where it forms an irregular limit. No artificial deformation of either the forehead or the occiput is noticed, or of the scalp in general. The groove of the eye is small; the mongolic fold well pronounced, the lacrimal caruncle being the most part of the upper eyelid. The base of the nose is very wide, but not too low; the side wide and straight; the tip quite wide, rounded; nostrils visible from the front. The mouth and the jaw, in general, are salient; lips somewhat thick. Of the ear we can distinguish only a little, being quite disfigured by a mange eruption.

Number 2 is a middle-aged man, robust and well-developed. The scalp is of interest, mainly due to it characteristic hypsicephalic shape. The forehead goes obliquely backwards; occiput quite perpendicular upwards. The narrowness of the cerebral capsule and of the whole scalp, compared to his height, is surprising. It is always interesting to observe in the living this scalp shape, which we are used to see only in the dead material. Not taking this into account, the considerable height and the pronounced narrowness are a distinctive feature of this individual's head.

Going through the details, the hair is black, well developed; the forehead is very narrow and relatively high; the limit of the hair is irregularly lost.

Supra-orbital arches of the frontal bone do not come out. The groove of the eyes is oblique, very narrow, thus the pupil, very deep in the orbit, is not so visible. This impression is even more pronounced in the base of the nose -which is very high- and by the very salient zygomatic arches.

The nose is of medium to small proportion, the right side with a little elevation at the half.

The mouth part is not salient; lips being narrow and the upper lip very well arched. Cheeks are deep-set.

Over the upper lip there is a slight inflammation and in the middle part of the inferior lip, a small lock of hair (*mosca*); over the chin a true goat beard.

The ear is totally stuck in the scalp and the antehelix comes out a little in the middle; but apart from this there are no specificities.

Reserved, taciturn physiognomy" (Bruch 1904).

Almost at the end of his report, Bruch brings other objects, this time subjects-objects that, in Bruch's words, are related to the past in a different way to knowledge: they are the descendants of the former owners. Are these, then, the inheritors of Hualfín? Well, not exactly, and here is an unspoken relationship. Descendants appear in the text as objects assisting knowledge of the past "in order to give us at least a hint of what they were like" (Bruch 1904), that is, their link with Hualfín is in the order of knowledge, not in the order of society. They are not the agents who own the lands divided by the rows of trees, but the objects appearing to help us know their ancestors, the former owners. That is why they do not speak, and they do not even have a name, because Bruch's interest in them is not in what they say as agents of history, but in what they are as objects of history, a history that can be known and told by observing and describing the remains and ruins of their ancestors, as Bruch says, "the last vestiges."

Between mute descendants and ancestor-owners, there is a gap, a metaphysical rupture, which can only be mediated by knowledge or, more specifically, by a particular kind of knowledge, the study of the mute material remains. This metaphysical rupture between history and the descendants is what makes them irrelevant as agents of history or as agents of society: the land of their ancestors taken by colonial violence; they are also deprived of the word about their relationship to their ancestors, to the remains and ruins, by an epistemic violence (Spivak 1988) that Bruch, and this tradition of archaeology as a whole, institutionalized.

Knowledge of the history of Hualfín that Bruch begins is heir to a tradition that, 25 centuries before, was started by Herodotus of Halicarnassus, who established as a theoretical-methodological basis of Western historiography, a hierarchy of the sources of knowledge in which the testimony in their own language on the gaze over others prevails (Abercrombie 1998). For Herodotus, only those testimonies based on direct eyewitness were valid and would be considered, subordinating thus other sources of knowledge, such as oral memory. History was, moreover, a business run by members of the same linguistic-cultural region (also a political-military region); it had to do with war relationships between this and the barbarians that, by virtue of their linguistic and cultural difference, were the object of war rather than dialog, the peoples without language. Combining these two structures, the logical result is

that the history of the war against the Persians excluded the voice, the look, and the memory of the Persians and that history inhabited a particular dwelling, "ours," that of the victorious conqueror, and from this dwelling history was written, even when it was ostensibly written as a mere knowledge relationship of the facts of the past.

Bruch relates himself to the remains and ruins in the same way as he relates with descendants: material remains and descendant remains are there, and Bruch is here to know the past through them. The fact that the remains are in Hualfín, as well as the descendants, does not affect Bruch except as a knower, that is, by taking the role of a knower he denies any other ontological or social relationship between the living and the dead (Haber 2009). It is not that Bruch should be held responsible for the colonial violence exerted over the ancestors of the descendants, but that his delimitation of the relationship in terms of a knowledge relationship, that is, not a social one, also delimits the social relationship between ancestors and descendants: between those who suffer the consequences of colonial horror that he describes as mute, reserved, and taciturn objects and those who enjoy the benefits of those same consequences, the landowning elite who hosted him in their houses, whose dividing tree rows he observes, and whose laborers posed for his photographs and excavated the sepulchers of their ancestors. This is a delimitation that archaeology naturalizes not in its theories or its thematic contents, but in its disciplinary frames: the subject matter – the long gone past – and the method, material remains, mute, and inert matter. This marks a delimitation which excludes the social and ontological relationship existing between ancestors and descendants and which ultimately perpetuates the present consequences of colonialism.

Bruch seems safe from the machinery that builds subjectivities divided from history. I say "seems" because the sin of *hubris* is soon discovered by the inhabitants in the Olympus, who claim which all mortals should know: archaeology, even as a business aimed at knowledge, must be justified for the present society. Bruch's last phrase reveals himself trapped in the hegemonic erasure of history: "Of course there is a lot to be found out about those regions, which yet hide the richness of *our* prehistory" (Bruch op.cit., italics added).

Bruch enunciates prehistory in the first person plural, including himself in a "we" that relates then, to the past of Hualfín, in ways which, delimited or not by knowledge, are enough to define a collective "we," an agent of prehistory, unveiling thus the metaphysical character of the fracture, that is, the colonial subjective difference transposed to the objective world, because a collective of knowers – the collective of archaeologists – is not under consideration here, but of a social collective, the Argentinians, who consider themselves agents of a history they describe as object. The same as Herodotus with his methodological premises, Bruch, and archaeology after him, uses his premises in such a way that, under the pretext of knowing a past, he constitutes his own identity, his own home address: archaeology unveils the historical richness of the liberal Argentine nation that, at the same time, recapitulates European colonization and Western civilization.

What Bruch's text illustrates is the procedure by which the modern archaeological discipline incorporates and reproduces the specific place from which it develops as a discursive practice of the histories and cultures of the others; this is not just in the choice of one or another theory, one or another paradigm, but in the delimitation of its subject matter and its basic methodology. A place whose representation under universal interests of knowledge is nothing but a mystification of concrete social relationships, a cared-for blindness towards their own social and historical conditions. The fact that, from then on, archaeology is considered a purely scientific practice is nothing but the remark of this modern discipline. From this point, from that particular social and historical place of which it is blind, archaeology intends to instrumentalize itself towards intervening in the transformation of social situations, thus the activation of such discourse in a colonial project. But in order to understand the circumstances in which such a process of post-disciplinary instrumentalization of archaeology works, it is necessary to research deeper into the postcolonial context in which life's discipline gives birth to its

regulation, because state and science do not discipline social relationships now so much as they modulate them (Lazzarato 2006). That which modernity had enthroned as the primary relationship with the world, that is, knowledge, is reconsidered in postcolonial moments as the pole of hegemonic normality from which science and state modulate social relationships. Life, permeated now more than ever, faces the penetrating strength of the free market.

Archaeology, in effect, functions to discipline the relationship with history and the ancient world; so long as it is posited in terms of rigorous knowledge, the metaphysical and essential break between history and its consequences has produced agents estranged from memory as well as mute, methodologically easy-to-manipulate material objects, not linked to social relationships. Agents and objects distanced from each other through a Cartesian discipline are reconnected when incorporated as agents and objects of an emergent neoliberal faith, according to which the free market replaces Christ and the reason as poles of hegemonic normality, re-magnetizing and reorienting preceding discursive and disciplinary regimes.

Archaeologies oriented to tourism development, to the production of new market goods, and to the growing market integration of farming and/or indigenous peoples, and the administrative regulation under the scheme of impact assessments of colonial megaprojects such as those of the mining and extractive industries, proliferate nowadays in the ever expanding field of social archaeologies, a space which was formerly taken by archaeologies oriented towards spreading in society the creed of disciplinary knowledge. It is not that archaeology has stopped its tribute to the expansion of colonial borders, but it renews its services as this border rearticulates under new mechanisms directed to old goals: the land of the blood and the blood of the land.

Having reached this seeming endpoint, the question arises: over what and whom is that border growing? If upon each side of this emergent border the same denomination existed, there would not be any sense in talking about a border, about new markets or different developments. On the other side there is that which maintains more or less manageable links with the forces of the free market, that which is to a great extent dominated and contained, and that which is designated by the hegemonic place of power and science, which Bruch describes as reserved and taciturn. What knowledge is it that the reserved ones keep to themselves? From what/who are they withholding? If they are taciturn, what is the implicit message in this silence? For colonial figures such as Bruch, what could barbarians talk about, can they enter within the epistemic field, and when their speech manifests as noise? This tacit place of withholding is a discursive space marking a critical point of entry for the genealogical examination of power at work in archaeological practice.

Undisciplining Archaeology in the Puna de Atacama

From the mid-1980s, I started research in the region of Antofagasta de la Sierra, in the Puna of Atacama. Early research concentrated on understanding the ethnography of the relationships between local population (mainly adult males) and flock animals (sheep and llama), pastures, as well as vegetation and landscape. Back then my aim was to pursue ethnography as a means for archaeological interpretation, inserted into what processual archaeology understood as ethnoarchaeology (Haber 2001). Only a few of the assumptions guiding this initial program remained in the wake of being confronted with local knowledge. None of the avenues for the observation of reality (e.g., economic strategies) or the enunciation of categories for the objects under research (e.g., shepherds) manifested in the conversations I had with my field teachers. Waste management, for instance, would have only been superficially and acceptably considered within the pattern of bone disposal, objects, people, and their movements seemed to obey to logics completely unrelated to the strategies and logistics I was initially determined to discover as a contribution to my discipline. All of this made me, progressively, leave aside the restrictive aspects of archaeological practice which had been imposed upon me. The discipline was not in the

least prepared to listen to the people or to question disciplinary assumptions from the local perspective and/or indigenous knowledge that confronted a great deal of institutional disciplining. I was forced to academically distance myself once I began to question the assumptions then held (and still existing) on the domestication and pasturing of llama, taking into consideration instead the meaning frames provided by the Aymara and Quechua languages and by the semiosis of local practice in relating with these animals (Haber 2001).

Through the 1990s I undertook my doctoral research, in the same region but in a different area – Antofalla. I intended to examine the past by putting into play theoretical-methodological resources which would not presume an economic-liberal logic, an evolutionist linearity, or a history determined by external forces such as evolution and empires. I believe the most valuable feature of this research was to put, in a house I excavated in, the place from where to look at the world and tell the history. And history, seen and told from that house, had a very different flavor to that with which was being told at the time. The histories of that time highlighted the continuities of farming life over the succession of cultures, periods, and stages of growing complexity. From the house, the smell of food, the shovel with which ditches had been dug to water crops, and what the talk on the neighbors was were more important than the domination of humans over animals, empires over towns, and functions over meanings. This was also, to a great extent, a disciplinary research, in that its aim was to know the remote past through its mute objects and their relationships. When I put those objects in conversation, I did it, when I could, through my dialogs with local knowledge, but I also kept within myself and took strength as interpreter and mediator, intentionally not listening to local memory techniques. This research also had the virtue of incorporating local theories to the relationships between beings in the world confronted by Western theories, but even so, I continued as a mediator between local knowledge and the archaeological. I obtained my Ph.D. with this research and then I was ready to learn.

One of the main sites of learning for me was the public hearing held in Antofagasta de la Sierra in October 2002, in which the government of the province of Catamarca put forward the project for the creation of Las Parinas National Park for the consideration of the local population. A couple of years before, the project of creating the park was being prepared, but I did not take part in it nor was I invited to do so, as I believe, because I did not clearly express myself in favor of the idea when I was consulted by the senator who promoted the initiative. Some weeks before the public hearing in Antofagasta de la Sierra, there was a meeting at the National University of Catamarca in which technicians and officials of the Secretary of the Environment of the Province of Catamarca presented the project. A group of students from Antofagasta living in the city had been invited to the meeting, and my suspicion about the project and its future grew when I could confirm that in Antofagasta no one was aware of it.

Several researchers were invited to the public hearing, including the four directors of archaeological research teams in the area where the park was to stand; some biologists, ecologists, and ornithologists; as well as officials from the National Park's Administration. In the group of technicians and academics, voices were heard clearly from those in favor of the park, to those worried about the lack of awareness on the part of the locals. Among the locals, on the other hand, there was great mistrust expressed in fears as to landownership and the possibility of the field being fenced. As I saw it, these fears were easily defused by the project creators, but the distress remained without the people being able to express it.

With two colleagues, I took part in an informal meeting held in a private house, where some of the most well-known elders in town were congregated. They said they disagreed with the project and mistrusted it: "if we are the ones who give protection, why do we have to see them come and tell as how we have to do things?" The place from where their rejection of the park emerged was the same local theory of relationality that appeared in my ongoing research. According to such a theory,

appropriate relationships between beings are always reciprocal and asymmetrical and consist of a complex mixture of upbringing, respect, love, and fear, all occurring at once. Thus, ownership and love, caretaking and breeding, and agriculture and ritual are enacted as part of the same kind of appropriate relationships. Conversations evolved, comparing the local vision to the vision of the promoters of the park (which could be called a *modern* one), according to which the land is there to be known by the scientists, who determine how to manage it. This transformation that can seem obvious for an academic context, so natural as a hegemonic practice, is not as intuitive for those who are debating resistance to modernizing discourses from the other side of the colonial border. Revealing and moving as the knowledge about the local theory of upbringing of life seemed to me, in that context, putting into words academic assumptions as to their link to the environment in terms of a theory was also enlightening, because enunciating the hegemonic position can produce its detachment from its presumed site of normality (Castro-Gómez and Grossfoguel 2007). Protection and breeding (local) relationships were compared to biopolitical hegemonic (state) relationships, these being the ones that gave substance to projects centered around the production of life.

Local vocality was strongly expressed in the following public meeting: the park was rejected by the population, which adopted, apart from that, other meaningful political gestures – such as spitting at the French ambassador who had politically promoted the National Park, because of an international touristic project involving his own company, and ultimately throwing him out of the town. It was witnessing these 2002 events that allowed me to understand the extent to which local frameworks were intimately intertwined with the reproduction of local life and the particular quality of suffering when life was at risk due to colonial projects. I also examined how politically positioned academic disciplines are, and among them archaeology, certainly functioning as a key part of the colonial arsenal. From there, I noticed the urgent need not just to deconstruct the disciplinary framework in terms of a critique of possible knowledge conditions as I had done thus far, but the need to take such a deconstructive project in the direction of my current work, a positive project of disabling the colonizing aspects of disciplinary practice and knowledge (see Haber 2009). And this is a collective task, not simply because of the quantity of people involved, but because it is a task of decolonial activation since it is collaboratively done with populations affected by colonial projects.

Where does archaeology stand in these postcolonial encounters? As I have stated so far, archaeology occupies a privileged place in the colonial arsenal. That is why it is necessary to deactivate it, in addition to locating and delimiting its work. And for archaeology, there is no better medicine than local interlocution, that is, to make archaeology have a conversation with the silenced voices over which it has been built. That is precisely what I intend to do in different fields of activity. With my students of "research design," we try to structure archaeological research as having dialogs with local contexts and voices, having the archaeologists communicate with the locals in their terrain, but firstly with their own town. In the 2006 edition of the course, I was guiding my student Daniela Fernández to begin researching methodological procedures and assumptions in the studies of archaeological impact. My guiding rationale in the context of best field practices was that by raising the quality and standards of such projects to the levels equivalent to those of the home countries of mining companies, including ethnic-relevance criteria and not just academic ones for the consideration of the affected cultural patrimony, and making impact studies easily controllable by the interested parties, then at least one of the aspects of large-scale mining could be controlled that which is concerned with cultural patrimony. Daniela then gave her vision of the issue as an inhabitant of Andalgalá, the town soon to be significantly impacted by a large-scale mining project whose 3.6 km wide open pit will be set only 20 km from the town: the sense of cultural patrimony disappears if the heirs of that patrimony disappear. Who is the archaeologist to say where our patrimony is located, Daniela asked, to say what is worth saving and what is not? Who is

the archaeologist to intervene in safeguarding our patrimony in the procedure by which he gives a permit to a project, the same that will lead us to death? Why do they measure the impact over my patrimony of a project that will terminate my offspring? Archaeological patrimony and cultural patrimony are not different from the land or the community; you cannot save one of them by destroying the other. Again archaeology, construed from the local viewpoint, loses the commonsensical autonomy that justifies its modes of intervention, be it as discourse or as project, in local life. This circumstance, as Wilhelm Londoño suggests, is the starting point of an alternative definition (*pers. comm*. 2012), another way of calling what I am naming here "intercultural."

As the reading of Bruch's text informed by local conversations shows us, the discourse of cultural patrimony goes hand in hand with the denial of the patrimonial relationship between ancestors and descendants of the same land. That is why the epistemic de-linking work (Walter Mignolo and Catherine Walsh) as well as the task of distinguishing the thought not from the contents but from the terms in which Western thought is contained; I repeat, the epistemic de-linking work is just the visible tip of the iceberg. Such a de-linking exists only if it occurs in conversation with local knowledge, because they are the ones intimidating epistemic safety, shaking the basis, and questioning not just of thought categories (the coloniality of knowledge) but the ontological place of thought (the coloniality of being). However, knowledge presupposes a de-linking from modern categories, as a leap into the void, and it is a thought located from places-other, already attached to the place, to the land. Thus, de-linking, if it occurs while listening to the Other in the field (developing social relationships) and not just interpreting the Other in an office (developing knowledge relationships), implies a relinking from a place which is not the border itself but the other side of it, the other side of the metaphysical rupture.

The archaeological-it, for example, is on the Other side something linked to local vital relationships, although by following a relationship of networks and theories completely different to the disciplinary ones. With those assumptions, my relationship to Antofalla advanced along local political strategies of presentation before the government as an indigenous community which claimed the communal property of their land. Following this, what archaeology considers its subject matter of study, and that in an intercultural dialog would lead to de-linking, is, in Catamarca's local communities, already linked to life-in-relationship; it is an integral and vital part of the territory, this last taken not only as a geographical space where a community is located but as the time-space that interacts as an agent which is sensitive, protective, powerful, and demanding of hierarchical reciprocity obligations with a collective of people.

I saw myself involved in local political strategies, neither as researcher or militant, because both roles instrumentalize the relationship, the link, following their own aims, of knowledge and ideology. This happened more due to the fact that my role of inhabitant makes me a part of these relationships, and from there my interest could be put with (i.e., composed together with) those of the community, as I am an active part of the processes. The times of these processes cannot entirely be managed by me; they are, on the contrary, as in any relationship formed by different people, very uncertain. The community has its own times and processes, many times different to mine and even opposite to my own political logic.

Can I say I have a social commitment to this community? No. What I have, or, better, what we have, are social relationships. Of mutual knowledge, of interests sometimes shared, of comradeship, mostly of friendship. I feel that friendship with actual people is what moves me, more than the objective of improving the people's life. I do, instead, feel politically committed to decolonize my own place, to decolonize myself, or subordinate, as well as subordinating relationships. In this way I understand archaeology as a political practice. I am not interested in moving my academic and intellectual resources to reach politically defined aims, but intercultural interlocution politically moves my academic and intellectual

resources to the point of demanding political, cultural, and ontological positions.

Many of the relationships of the communities with the meaningful lives in their territories have suffered colonial extirpation politics. The judicial apparatus of the state, with its regulations for mining and for fauna, environment, and cultural patrimony protection, together with migratory and customs politics, establishes as a felony the relationships of Antofalla people with minerals, *vicuña*, birds and their eggs, the ancient, and the Chilean and Bolivian, recapitulating the legal and political context of Spanish dominion, when relationships with the gods and the language were also repressed. Taking all of this into account, almost everything people practice as culturally meaningful engagements with local cosmologies and landscapes necessarily enters into what the state typifies as a felony. Since the phonetic resemblance between the English language *de-linking* and the Spanish language *delinquir*, i.e., to commit an offence punished by law, I would like to play here with a possible alternative meaning of epistemic de-linking. Some years ago I met one of my peasant teachers while he was gold panning in an abandoned mine whose archaeology I was researching. Even as I was the intruder in his land, I had state permits for the excavation, while he hadn't any legal protection for the gold panning. As it is the case when someone hunts for a *vicuña* either to make an offering to *Pachamama* or Holy Mother Earth, or feed the earth, or receive the souls and feed them, or celebrate the ancients that grant treasure, this was a situation in which de-linking implied the separation of the judicial and the disciplinary categories for the enunciation of the world, from the things as they are presented in the world which implied a crime or, at least, an active complicity in the illegal. A couple of years later, I came across Andrés (Fictitious name) and we had a conversation in which he asked me if I could tell him the truth – given the fact that I was an archaeologist and university professor – whether or not the ore vein grew at night. His question demanded from me a political, epistemic, and ontological repositioning. Being an academic and thus forced to be permanently serving the truth, I understood the enormous degree of demand the question implied. The appropriate care and feeding relationships with the ore vein to make it develop, and at the same time give origin to rights that, far from being made objects in titles, are intersubjectively constituted: the protector is the owner, that is, he loves his creature, who at the same time breeds the breeder and is, finally, his owner. Andrés was asking me about my position in relation to local theory and as to the colonial differential in that theory whose rights are subordinate, and another theory, the state and science theory, which establishes physical-chemical and property relationships, sustained in mercantile acquisition. I often remember this situation because it eloquently exemplifies the circumstance by which there is no neutral place for archaeology, and that being already constituted in the field of power, it cannot be separated from its origin without linking it at the same time to a network of meaningful relationships. These, even when local, can also be mine to the extent to which the intercultural practice has as a precondition the opening towards transformation, to inhabiting the conversation. The immense literary task of archaeology, perhaps the most politically significant of all that can be proposed, consists in narrating the departure from one's own home address of thought and writing.

And it could not be otherwise. Because undoing that which had been sustained in the denial of intersubjective communication, as in the case of archaeology, means entering the conversation, having a dialog with the objective world where the difference that constitutes colonial subjectivity had been transposed as if it were a metaphysical rupture, sooner or later, moves that subjectivity. Intercultural research consists in a conversation about biopolitical techniques for the disciplining of relationships with the gods and people, and that is why it is a conversation that moves our relationship with them. To move the home address of writing is as much an effect as an effectuation of intercultural archaeology, as much a description of the place of the thought and the practice as a political provocation of my own ignorance.

In addition to describing my place in archaeology, I could describe it as undisciplined,

intercultural, and subjunctive. It is *undisciplined* of its most basic and permanent disciplinary assumptions, its objects and methods. It is undisciplined with regard to its assumptions about inert materiality and temporal linearity as the prime organizing modalities of the archaeological past. It is *intercultural* because it develops in open transformative conversation between frames of meaning and cultural assumptions, in a conversation which is in charge of the power differential historically built, a conversation as much inter as intra-subjective, because in post-colonial contexts we are all diglossic. It is *subjunctive* because it does not intend for the indicative description of an external reality, but it acts on as much internal as external a reality.

Future Directions

Now I would like to finish as I started, and for that I would have to emphasize that the description of some of my practices does not try to be a justification of my archaeology in terms of a commitment to the well-being of anyone, but nor is my field practice based in an aseptic commitment to an imagined truth of the object. If such a commitment exists, it does so with inhabitation. Inhabiting is always-already local and relational; it happens in a place and in conversation. The necessary location of inhabitation makes it impossible for me to theorize beyond the locality of my home address, but it is in that scale that the conversation seems relevant to me. A conversation in which other times and other spaces knit their voices, they are located. Being an inhabitant, being there, bringing up the local life, all these define to a great extent my way of doing archaeology. No science can ask for a complete justification in an unfair world. I may be interested in other mythologies; they can propose versions of the world to me that originate the inside of things and give myself and my world some good and necessary subversions. At moments in which faith in the free market seems to replace faith in reason (which in time replaced faith in salvation), a return to the land feels necessary. Intercultural archaeology becomes a conversation which feeds an emergent counter-hegemonic, decolonial, and anti-capitalist sensibility. An old-fashioned conversation emerges, one outside any one normal framework, one fundamentally constitutive, a conversation with that thirteen-year-old girl and that middle-aged man whose teachings Bruch did not acknowledge in Hualfín, with their ancestors and ancient gods, those who survived protected by the shadows, buried in sands and bushes, named in silence, and fed in secret.

Interdisciplinarity and Archaeology

Ariane Maggio
University of Western Australia, Crawley, WA, Australia

Introduction

Archaeology is a scientific field which since its first inception has always been interdisciplinary. Archaeology draws on the knowledge, data, and methodological techniques from a variety of different disciplines within the human, social, and natural sciences. These include anthropology, art history, chemistry, geology, genetics and molecular biology, heritage studies, history, indigenous studies, information technology, museology, palynology and botany, paleontology, philosophy, psychology, and zoology. In short, if the knowledge and methods of any particular discipline can be applied to the study of the human past or human ancestry, then they can be incorporated into the archaeological toolbox. The interdisciplinary nature of archaeology brings with it a host of discipline-specific ethical considerations, notwithstanding the existing key ethical dilemma of archaeology, relating to who owns the past. Further to this, the effective communication of interdisciplinary research to the public, and its relevance to society, plays a key role in the ongoing drive for innovation and thus interdisciplinarity in archaeology.

Definition

"Interdisciplinary" is defined as involving two or more academic or scientific disciplines. "Interdisciplinarity" is defined in this entry as combining two or more (usually) academic disciplines into one project or activity.

Historical Background

Historically speaking, the field of archaeology has always been interdisciplinary, first drawing on the disciplines of history, cultural anthropology, and geology for methods and interpretation. For example, the ethnography of modern day hunter-gatherer societies has a long history of being used by archaeologists as a proxy to interpret archaeological material from past, long extinct, and usually prehistoric, hunter-gatherer societies in the absence of historical records (Pluciennik 2014). There is an entire sub-discipline of archaeology dedicated to the archaeology of the historical period, after the advent of writing, known as historical archaeology, where documentation can be used to interpret (or as a part of) the archaeological record (Hicks and Beaudry 2006). Archaeology as a discipline started through the collection of artifacts from past societies, typically those relating to classical history or myth (Bahn 2014). It was then the domain of antiquarians who collected artifacts for personal display and was usually the domain of the wealthy. Archaeology would then be significantly changed in the nineteenth century CE by the development of stratigraphy, a branch of geology where the relative position of sediment layers and their relationship to the geological timescale have been co-opted in archaeology for the analysis of the order and position of layers of archaeological remains (Balme and Paterson 2014). The increasing professionalization of the discipline in the early twentieth century CE, the development of the grid system

of excavation, and the use of absolute methods of dating material (such as through radiocarbon) would then lead to the emergence of the modern discipline of archaeology as we recognize it today (Bahn 2014). Interdisciplinarity in archaeology has also been a driving force to shape archaeological theory, with the use of radiocarbon dating and ethnography being linked to the rise of processual archaeology and the incorporation of theoretical approaches from fields such as philosophy, gender theory, and sociology incorporated into post-processual archaeological frameworks. The modern discipline of archaeology draws on the techniques and knowledge of a wide variety of different disciplines, from tracing diet and origin through chemical analysis of isotope ratios, using microscopy to analyze tool marks on hand axes, mapping sites using geographical information software such as ArcGIS or LIDAR, and through the interpretation of past societies using archaeological theories drawn from psychology and philosophy. Thus, it should not be altogether surprising that with the constant advances in modern science and technology and the demands for innovation within the scientific and academic spheres, the interdisciplinarity of archaeology continues to increase over time.

Key Issues/Current Debates

The persistence of archaeology as a discipline is deeply rooted in the public interest in the human past and what makes us unique. Without this interest, there would be a critical lack of funding for archaeological projects, programs, and public museums. Therefore, it is not surprising that the interdisciplinary nature of archaeology is also the result of public interest and engagement. Interdisciplinarity in archaeology relates not only to integrating different types of disciplinary knowledge to the study of the past but also the effective communication of this knowledge to different audiences, be they academics from other disciplines, the general community, stakeholders, government, or industry (Frodeman et al. 2017). In this way interdisciplinarity is a form of academic innovation meant to increase the relevance of our work to the audience it is presented to, a bridge if you will, between academics and wider society (Frodeman et al. 2017). Innovative uses of techniques and knowledge from other disciplines help to keep the field of archaeology fresh and relevant to the general public and bolster public interest (and funding) for our work, thus keeping the discipline alive. One example of this is the use of virtual reality in museum exhibitions to reconstruct sites and give audiences an in situ glimpse of areas that are at risk of destruction or are inaccessible to the general public, such as the Mogao Grottoes in Dunhuang, China (Greuter et al. 2016).

Research projects that are interdisciplinary are generally perceived as being more widely relevant to society. Take, for example, a standard archaeological excavation of a rock shelter in the middle of the Australian desert. This may be of interest to archaeologists, indigenous communities, or members of the public with a general interest in the past. If the project also involved artistic and chemical analyses of the rock art of the cave, those with an interest in rock art would also become engaged, in addition to those with an interest in chemistry. Add in ancient DNA analysis and you have the attention of a lot more of the public, due to the "sexiness" (for lack of a better word) of the science and the current public interest in ancestry studies. This interdisciplinarity also provides more information on the past use of the rock shelter than a traditional excavation alone as it is more comprehensive, and it may also better serve the local indigenous community working to protect their cultural heritage within a legal system which privileges science over oral history (McNiven and Russell 2007). Interdisciplinary projects in archaeology are now more increasingly commonplace and often are a requirement for receiving competitive grant funding – see, for example, the Australian Research Council's *Statement of Support for Interdisciplinary Research* (2018). The reason for this relates back to the push for innovation and the wider marketability and relevance of archaeology to society. This entry will touch on some of the more recent interdisciplinary approaches to archaeological knowledge and practice, such as archaeogenetics,

cultural heritage management, digital archaeology, and human remains recovery and analysis. These have been selected as they are not only interdisciplinary but also attract significant community or media attention and often involve community collaboration.

Ancient DNA and Archaeogenetics

The ability to extract and sequence DNA has led to the creation of a completely new sub-discipline of archaeology known as archaeogenetics. Archaeogenetics utilizes techniques and tools from the molecular sciences to analyze the genome of past humans, animals, bacteria, and plants to gain a potential plethora of information about the past (Matisoo-Smith and Horsburgh 2012). Advances in molecular science have also allowed for the analysis of trace amounts of DNA to be sequenced relatively affordably, when previously large samples were required and sequencing was time- and cost-intensive. DNA analysis can be completed through the extraction of DNA from archaeological material, such as the skeletal remains from a burial. Archaeogenetic research can be done through comparison of the DNA extracted from past populations, with DNA obtained from living populations, in order to estimate the timing of migration events and trace lineages back to an origin point (Matisoo-Smith and Horsburgh 2012). DNA can also be used to link living populations to past populations and has been used in legal proceedings to determine shared ancestry between a living community and excavated skeletal remains and to determine if contested skeletal material should be repatriated to a given community claiming to be their descendants (Matisoo-Smith and Horsburgh 2012). Archaeogenetic studies are not merely the work of archaeologists with knowledge of molecular techniques; however, some are completed by molecular biologists without any archaeological knowledge. When interdisciplinary collaboration between molecular scientists and archaeologists does not occur, mistakes can be made; molecular biologists may neglect the context of the material being analyzed or not have access to reports or archaeological literature, while archaeologists may lack fundamental knowledge about methodology, genetic study design, and particular caveats to molecular science research (Lebrasseur et al. 2018). An example of this is shown in an archaeogenetics study of Neolithic graves from the Carpathian basin which were misdated to 6000 years earlier than they should have been, due to the molecular scientists not fully incorporating the archaeological literature and grave context of the skeletons that was used for the genetic analyses (Bánffy et al. 2012).

With DNA testing becoming more accessible to the general public, it is possible to send a mouth swab off for analysis and have your DNA assessed in terms of your ancestry, with the subsequent report including mitochondrial DNA, haplotype analysis, and percentage of Neanderthal or Denisovan DNA. This is usually without proper archaeological context, and usually with insufficient explanation of the caveats of the method, and can lead to problematic interpretations of ancestry (Royal et al. 2010). However, the demand and use of these publically accessible DNA testing kits clearly illustrate the public interest in ancestry studies and thus the interest in interdisciplinary archaeogenetic studies which provide much of the contextual information that is used for the ancestry reports. Furthermore, the media attention surrounding molecular studies of human origins and hominin genomes shows that the interdisciplinarity of archaeogenetics has considerable relevance to the community.

Cultural Heritage Management

Cultural heritage management is an interdisciplinary application of multiple fields of expertise, drawing on the practices of conservation, anthropology, indigenous studies, restoration, museology, archaeology, history, and architecture. Traditionally concerned with identifying, interpreting, maintaining, and preserving sites of significant cultural importance or physical heritage, cultural heritage management is also applied to intangible heritage, such as preserving traditional culture, languages, and skills (Brockwell et al. 2013). Cultural heritage management also overlaps with public archaeology, as much of the interest and the push for the preservation of cultural heritage come from public interest and

demand (Smith and Waterton 2013). Thus, the interdisciplinarity of cultural heritage management comes not only from the interdisciplinary application of these complementary fields under the title of cultural heritage management for the preservation of cultural heritage but also the effective communication of cultural heritage management projects and results to various stakeholder groups and the broader community. Stakeholders in cultural heritage management projects can include industry, such as mining/construction, agriculture, and tourism, government departments, academic institutions, indigenous/traditional owner groups, and the broader local community (Smith and Waterton 2013). Tangible cultural heritage management projects can include surveys to determine if any archaeological material is present prior to construction or demolition, rescue and salvage excavations to prevent the destruction of archaeological material without study, heritage curation and interpretation of material or sites, preservation, and restoration of sites. Increasingly, cultural heritage management is becoming more community focused, with a push toward greater collaboration and communication throughout all stages of cultural heritage management projects with the community (Brockwell et al. 2013). This allows for interdisciplinarity between the community and the cultural heritage management, thus building on the relevance of cultural heritage management to the community and ensuring the ongoing survival and funding of cultural heritage management projects.

Digital Archaeology

The increasing digitization of the modern world and the almost ubiquitous access to the Internet have introduced an interdisciplinary and highly innovative field of digital archaeology, combining archaeology with information technology and computer science (Evans and Daly 2006). The term digital archaeology can refer to the study of the recent past using technology, but it can also refer to the digitization of archaeological materials and records both during and after fieldwork. Digital archaeology allows archaeologists to produce digital copies and repositories of data, through such methods as photography, laser scanning, radiography, 3D modeling, and virtual/augmented reality (Evans and Daly 2006). The digital data can be shared between researchers and made available for the public to view via the Internet. The ethical issues with digital reconstructions of sites or materials are similar to that usually faced in archaeology, including who has ownership of the digital material, who controls the access to it, and is it ethical to restrict access to a digital reconstruction of a public site? However, digitizing archaeological material or data also allows for the public to view and experience sites that they otherwise would not be able to access, either due to location or due to other restrictions (Evans and Daly 2006). One poignant example of this is the photogrammetric reconstructions of the now destroyed site of Palmyra in Syria (Wahbeh et al. 2016). By making the material more widely accessible to the public, digital archaeology also makes it more relevant to them, being something that they can access and experience. Digital reconstructions can also be made interactive, a method which facilitates the effective communication of archaeological research data and interpretations between academics and the public, removing scientific jargon and making the transmission of information interesting and relevant to casual viewers.

Human Remains Recovery, Physical Anthropology, and Osteoarchaeology

The excavation and analysis of human skeletal remains can fall under both the disciplines of anthropology and archaeology (Lewis et al. 2012). The delineation between the two disciplines is unclear, as in the United States archaeology is considered a sub-discipline under the umbrella of anthropology alongside cultural anthropology and physical anthropology, yet in other countries (such as Australia), they are complementary yet separate disciplines. However, the analysis of skeletal remains brings with it the ethical issues regarding ownership of the past and respect for the dead and can cause ideological conflict between archaeologists/scientists who wish to preserve or study the remains and cultural groups who wish for the remains to be undisturbed, returned, and/or reburied

(White and Folkens 2005, and see ▶ "Human Remains: Ethical Issues and Historical Perspectives"). This is not just an issue faced by archaeologists working on indigenous sites but can also occur in communities with religious or cultural objections who view the excavation of burials as desecrating a grave or against their faith. In this, the wishes of the community should be respected. However, it can be particularly difficult for scientists who wish to study the remains for information regarding the past population (White and Folkens 2005). Technology has advanced, and with digital archaeological methods, there are innovative new ways to study human remains with minimal disturbance or potential destruction, such as laser scanning and computed tomography (CT). High-resolution CT scans can be compiled to produce 3D reconstructions of skeletal remains, which can be studied virtually or 3D printed and analyzed in the same manner that traditional casts used in the past (Thompson and Errickson 2017). This allows for analysis long after the remains have been repatriated and reburied. They can also be made available for study through online repositories, thus allowing for greater access for international scholars without having to travel to a museum to view the material. The interdisciplinarity of archaeological human remains recovery and osteological analysis is not only shown through the application of physical anthropology to analyze recovered skeletal material (known also as osteoarchaeology), or the digitization of skeletal material using techniques from digital archaeology, but through the collaboration and the communication at all stages of the project between researchers and stakeholder groups. Increasingly, this collaboration allows for greater interdisciplinarity particularly in the analysis of indigenous remains, where cultural practices and community concerns should be heeded and respected by archaeologists working with the material. Often destructive analysis of remains through methods such as isotopic or DNA analyses, or even long-term study of the remains, is not permitted by community groups; however, with effective communication, collaboration, and respect between researchers and the community, compromises can sometimes be reached, or alternatives such as CT scanning can be agreed upon, provided that the relevance to the community group is clearly understood.

International Perspective

In the past there has been a tendency to assume that Western scientific knowledge and interpretations trump that of the indigenous people of a given area (Scarre 2006). This colonialist view has a long and toxic history, both in Australia and across the world, and has led to significant distrust between some indigenous groups and scientists. This is particularly evident when the results and interpretations of archaeological work come into conflict with the beliefs of the local indigenous communities (Scarre 2006). One needs to only look at the protracted legal proceedings regarding Kennewick Man in the United States as a case study, where archaeological interpretation was, at the time, in conflict with indigenous knowledge and led to a messy debate over who has custodianship over the past and which form of knowledge is more important (Burke et al. 2016). In the instance of Kennewick Man, the increasing interdisciplinarity of archaeology proved incredibly relevant to the indigenous community, when an archaeogenetic study linked one of the indigenous communities to Kennewick Man via DNA, thus leading to the repatriation of the remains to the community for burial (Burke et al. 2016). As the interdisciplinarity of archaeology has increased, it has also become increasingly important, and rightly so, that archaeologists respect the wishes and cultural knowledge of indigenous communities, even if they find themselves in disagreement. However, increasingly in Australia archaeological studies of indigenous sites are often merely confirming what the indigenous people have already known through their own oral histories and cultural traditions, often for the sake of working within a Western legal system which again privileges scientific fact over indigenous knowledge (Mitchell et al. 2013). Thus, there is a growing push to decolonize archaeological science, through increasing collaboration with indigenous groups (particularly from the

beginning of projects) and the incorporation of their extensive traditional knowledge and stories as being equally valid and complementary sources of information about the past (Bruchac et al. 2010). For the sake of interdisciplinarity, indigenous traditional knowledge can be viewed as its own academic discipline, and thus archaeological research can, and should, incorporate this rich source of knowledge into projects and in communication with the public to further decolonize archaeology.

Future Directions

With the rapid increases in technology and the apparent push for ongoing innovation, it is hard to predict the future of interdisciplinarity in archaeology. On one hand, the push for innovation in most disciplines is fueled by the fear of a lack of future security, be it consumer interest or secure funding. On the other hand, interdisciplinarity can decrease as the academic community becomes more insular and picks up the markers of disciplinary culture, such as discipline-specific jargon, closed academic communities, journals, and conferences. The challenge for archaeology as an interdisciplinary field is to ensure that the interdisciplinarity of projects is maintained and practiced in the best interest of the community, with effective communication and collaboration. This open communication, a form of public archaeology if you will, ensures that the interdisciplinarity of projects does not form closed disciplinary fields with little to no communicated relevance to the community and other non-academic stakeholders, who drive the demand for interdisciplinarity and are often sources of funding for archaeological work. From an Australian perspective, the future direction of interdisciplinarity in archaeology is already underway, with increased collaboration and communication with community groups, in particular indigenous groups with the decolonization of the discipline, and the incorporation of traditional indigenous knowledge systems and beliefs as a valid source of archaeological data. It is important to recognize the many tools and sources of knowledge at our disposal and understand that the discipline of archaeology has always been interdisciplinary, and it is through this interdisciplinarity that we will continue to be relevant within society.

International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) (Conservation and Preservation)

Stefano De Caro
ICCROM, Rome, Italy

Basic Information

The International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM; http://www.iccrom.org) was established in 1959. Its creation was agreed upon at the 9th UNESCO General Conference in New Delhi in 1956 at a time of mounting interest in the protection and preservation of cultural heritage and in the spirit of the 1954 *Hague Convention*, the first UNESCO Convention on the protection of cultural heritage in the event of armed conflict. In line with its mandate to promote the conservation of all types of cultural heritage, both movable and immovable, ICCROM has always considered archaeology as one of its most substantial fields of interest. Such a tenet is reflected in the variety of professional archaeologists who have directed the organization over the years (Cevat Erder, Nicholas Stanley-Price, Mounir Bouchenaki, and Stefano De Caro). Harold Plenderleith, a British chemist and former Keeper of the Restoration Laboratory at the British Museum, was the first Director of the "Rome Center," as it was then called. This was thanks to his heavy involvement in the conservation of important archaeological material from such sites as Tutankhamen's tomb and Ur, in addition to his scholarly publications such as his comprehensive book, *The Conservation of Antiquities and Works of Art: Treatment, Repair, and Restoration* (1957; revised with A.E.A. Werner in 1971). ICCROM's statuary functions focus on training, information, research, advocacy, and cooperation.

Major Impact

Since its inception, ICCROM has been heavily involved in training and capacity-building in the field of conservation. The active participation of Plenderleith in the International Campaign to Save the Monuments of Nubia in the early 1960s, together with eminent Italian experts such as Paolo and Laura Mora, helped lead to a fruitful collaboration between the Rome Center and Italy that resulted in the establishment of specialized courses launched in 1968 on mural paintings conservation, organized jointly with the *Istituto Centrale per il Restauro*.

Archaeology, understood in terms of ancient architecture in a central hub of the ancient world such as Rome, has also constituted an essential component of the courses on architectural conservation that have formed the core of training launched by ICCROM: the international course on Architectural Conservation (ARC) from 1965 until 1998 and the international course on the Conservation of Built Heritage, organized on biennial basis since its launch in 2007. Archaeology was also a key component of the conceptual reading of Italian and European historic cities and as a tool for their conservation. It was one of the main topics of the "Urbanological International Seminar," held in the town of Jesi, in the Italian Marche region, in 1969 (Fig. 1).

International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) (Conservation and Preservation), Fig. 1 ICCROM logo

Based on a proposal of the then Director of ICCROM, Bernard Feilden and Vassos Karageorghis, Director of Antiquities of Cyprus, and at that time, Vice-President of the ICCROM Council, a conference on "The Conservation on Archaeological Excavations" was organized in Cyprus in 1983. The main aims of the conference were twofold: to review responsibilities in the field of conservation, with particular reference to the 1956 UNESCO *Recommendation on International Principles Applicable to Archaeological Excavation*, and to discuss the basic principles of conservation at an excavation. Fifty-six delegates, including representatives of UNESCO, ICOM, ICOMOS, and those from the Departments of Antiquities of many European and Near Eastern countries (Cyprus, Egypt, Greece, Israel, Italy, Jordan, Arab League (Libya), Portugal, and Spain), took part in the discussion on the principles of conservation. The proceedings of the conference include recommendations on the topic promulgated by the twelfth session of the General Assembly of ICCROM, held in Rome from 10 to 12 May 1983 (Stanley-Price 1984). The Conference of 1983 laid the foundation for a series of initiatives that have developed over time, addressing specific issues related to the conservation of archaeological heritage.

Regarding mosaics, the international course on the Safeguarding of Archaeological Mosaics (ICCROM, Rome, 18 September–13 October 1989) is a forerunner of a program that was later developed during a forum on "Conservation of archaeological sites. Techniques, strategies and tools: the case of mosaics" (ICCROM, Rome, 30 November 1992). The theme was taken up again in 2007, when the first planning meetings for the MOSAIKON program were carried out by ICCROM, in collaboration with the Getty Conservation Institute (GCI) and the International Committee for the Conservation of Mosaics (ICCM).

In parallel, as part of its activities at the regional level, ICCROM has been developing integrated programs for managing sites of cultural interest, involving specialized training and broader capacity building. In November 1997, as

a result of the collaboration on PAT96 (the first Pan-American Course on the Conservation and Management of Earthen Architectural and Archaeological Heritage), the International Centre for Earth Construction – School of Architecture of Grenoble (CRATerre-EAG), the GCI, and ICCROM established the collaborative initiative, named Project Terra. It was under the auspices of Project Terra and in partnership with the INC-LL (*Instituto Nacional de Cultura-La Libertad* (INC-LL), a regional agency of the *Instituto Nacional de Cultura del Peru*) that the *Segundo Curso Panamericano sobre la Conservación y el Manejo del Patrimonio Arquitectónico Histórico-Arqueológico de Tierra*, PAT99, was hosted in Trujillo, Peru, in late 1999.

The ATHAR program on the conservation of archaeological heritage in the Arab Region (initially in Syria, Lebanon, and Jordan) was launched through a coordination/planning meeting on "Education and Curricula Design in the Field of Heritage Site Conservation," held in Beirut, Lebanon, from 16 to 17 September 2004. The program has since expanded to other countries and has recently established a Regional Centre for the Management and Conservation of Cultural Heritage in the Arab States and based in the Emirate of Sharjah. For the establishment of the ATHAR Centre, an Agreement of Implementation was signed between the Government of Sharjah, UAE, and ICCROM on 11 September 2011.

In the same period, a series of training initiatives were launched in Southeast Europe, starting with an introductory course in Archaeological Conservation, held in Belgrade, Serbia and Montenegro, from 4 to 6 December 2004. This pilot initiative was followed by a series of regional courses on Archaeological Conservation in Southeast Europe, held in Serbia and Montenegro (2006) and in Albania (2007).

In Asia, ICCROM contributed to the "Training Course on Preservation and Restoration of Cultural Heritage in the Asia-Pacific Region – Archaeological Research Methodology and Analytical Methods of Ancient Remains." The course, held in Nara, Japan, from 23 October to 3 November 2004 was jointly organized by the Asia-Pacific Cultural Center for UNESCO (ACCU), ICCROM, and the National Research Institute for Cultural Properties in Japan. In April 2006, ICCROM contributed to the International Conference on "From Concept of the Past to Practical Strategies: The Teaching of Archaeological Files Techniques," held at Beijing University, China. The following training activities subsequently took place in the region: "Training Course on Cultural Heritage Protection in the Asia-Pacific Region – Research, Analysis and Preservation of Archaeological Sites and Remains," organized by ACCU in collaboration with ICCROM and held from 9 Sept to 9 Oct 2008 in Nara, Japan; the CollAsia 2010 International Course on "Conservation of Underwater Archaeological Collections," Manila and Subic Bay, Philippines, 7–25 September 2009; and the "Training Course on Cultural Heritage Protection in the Asia-Pacific Region – Research, Analysis and Preservation of Archaeological Sites and Remains," Nara, Japan, 7–10 September 2010.

In the Mediterranean, ICCROM activities pertaining to archaeology and conservation have involved numerous initiatives. These include technical missions, such as that to aid in the evaluation of conservation tests at the Archaeological Park of Foz Côa, in Portugal, 15–19 May 2006; the 18th Conference on Archaeology and Cultural Heritage in the Arab Region, held by ALECSO from 19 to 21 November 2007 (this included a special session on training in the conservation of World Heritage sites in the Arab Region organized by the ATHAR program and collaboration between ICCROM, ALECSO, and the World Heritage Centre); the Fifth International Conference on Science and Technology in Archaeology and Conservation in Baeza, Spain, 8–10 July 2007; a Seminar on Archaeological Site Management organized by the Aristotle University, Thessaloniki, Greece, from 1 to 3 February 2008; the Sixth International Conference on Science and Technology in Archaeology and Conservation in Rome, Italy, on 9 December 2008; a seminar on archaeology and education, "Creating Links of the Past to the Future: Cultural Heritage and Civil Society," in Barcelona, Spain, 31 March–1 April 2011; and the ICOMOS Hellenic and ICAHM Regional Conference on "The Future of Protection Heritage Management for Archaeological Heritage in Times of Economic Crisis," held in Athens, Greece, 23–25 May 2012.

International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) (Museums)

Grellan D. Rourke
National Monuments, Office of Public Works, Dublin, Ireland

Basic Information

The decision to found the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) was made at the 9th UNESCO General Conference in New Delhi in 1956, at a time of mounting interest in the protection and preservation of cultural heritage. ICCROM was subsequently established in Rome in 1959 at the invitation of the Government of Italy. It is the only institution of its kind with a worldwide mandate to promote the conservation of all types of cultural heritage, both movable and immovable. ICCROM aims at improving the quality of conservation practice as well as raising awareness about the importance of preserving cultural heritage. It contributes to preserving cultural heritage through five main areas of activity: training, information, research, cooperation, and advocacy.

ICCROM is an intergovernmental organization (IGO), existing to serve the international community as represented by its member states. Its intergovernmental status and constantly updated network of specialized conservation institutions and experts enable it to collaborate closely with organizations such as UNESCO and its World Heritage Committee, to which it is an advisory body. It is governed by a General Assembly consisting of delegates from all its member states, now numbering 129. The GA determines the general policies of ICCROM; it approves its biennial program of activities and budget, elects the council members, and appoints the director general. Other functions include approving reports on council and secretariat activities, determining member state contributions, adopting ICCROM's financial regulations, and approving changes to the statutes. The general assembly meets in ordinary session every 2 years.

The ICCROM Council has 25 members elected by the General Assembly. The members of council are chosen from among the best-qualified experts in the field of conservation and restoration of cultural property, taking into consideration the desirability of achieving equitable representation of the major cultural regions of the world and an appropriate coverage of the different fields of specialization relevant to the work of ICCROM. The secretariat of ICCROM consists of the director general and staff. The director general is responsible for the execution of the approved program of activities.

Major Impact

ICCROM has always devoted particular attention to interdisciplinary collaboration in conservation, involving scientists, conservators, restorers, archaeologists, art historians, curators, architects, engineers, city planners, and other allied professions. Exploring conservation issues in research meetings and seminars has led to publications, guidelines, and international training programs. The Center has established an international library and documentation center, which has become an indispensable resource of reference for research and training.

Regular Rome-based activities have increasingly been complemented by long-term international and regional programs. Together, these form a worldwide platform, combining technical cooperation with research, training, provision of information, exchanges of personnel, and raising awareness about heritage conservation. The development of long-term programs in collaboration with several partner organizations has increasingly emphasized the sustainable management of heritage resources and the strengthening of institutions in member states to this end. New Strategic Directions were adopted in 2010 and the Center will be moving to new up-graded premises in 2013. Further information is available on the website http://www.iccrom.org.

International Committee on Archaeological Heritage Management (ICAHM) (Conservation and Preservation)

Douglas C. Comer[1] and Willem J. H. Willems[2]
[1]ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Cultural Site Research and Management, Inc. (CSRM), Baltimore, MD, USA
[2]ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Faculty of Archaeology, Leiden University, Leiden, Netherlands

Basic Information

The International Scientific Committee on Archaeological Heritage Management (ICAHM; http://www.icomos.org/icahm/) was established in 1990 by means of the ICAHM charter. This charter is the only international document that deals exclusively with archaeology, save the UNESCO *Recommendation on International Principles Applicable to Archaeological Excavation* of 1956 (New Delhi). The ICAHM charter is binding for the professional members of ICOMOS. The New Delhi recommendation, on the other hand, is to be honored by all state parties of UNESCO and grew out of the *Cairo Act* of 1937 of the League of Nations and earlier recommendations of the League of Nations Assembly of 1932.

In 1985, the Nordic countries convened an organizational meeting in Stockholm to prepare a draft charter for archaeological heritage management. The first draft was presented to the ICOMOS membership in 1987 at the 8th General Assembly in Washington, D.C. In 1990, at the 9th General Assembly in Lausanne, ICOMOS accepted ICAHM's 1990 ICOMOS Charter for the Protection and Management of the Archaeological Heritage, which not only defined for the

first time the aims and the role of archaeological heritage management internationally but made ICAHM one of the ICOMOS scientific committees. The charter stressed the integration of archaeological programs and planning, the creation of inventories, the importance of in situ preservation, and, when this is not possible, the responsibility of developers to ensure that proper archaeological investigations take place. Its influence is seen in the 1997 Code of Practice of the European Association of Archaeologists and in the 1992 European Convention on the Protection of the Archaeological Heritage (the Malta Convention) from 1992.

Of the almost 1,000 sites on the World Heritage List, approximately 80% are inscribed because of cultural values. Many of these (e.g., Petra, Machu Picchu, Pompeii, Angkor) are explicitly seen as archaeological sites, but all contain valuable archaeological components. In every historic city, there is a "city beneath the city," an archaeological trove. Further, many sites inscribed on the World Heritage List due to their outstanding natural resources also contain archaeological sites. Therefore, ICAHM has become perhaps the most active of the scientific committees.

Major Impact

ICAHM is primarily concerned with the implementation of Article 5 of the World Heritage Convention in regard to archaeological sites. Article 5 charges each signatory to the Convention to develop the capacity to manage, conserve, and preserve natural and cultural resources within state boundaries. ICAHM has focused on the following:

- To establish, promulgate, and encourage adherence to high standards and best practices for (a) management of archaeological sites and resources, (b) archaeological research, and (c) aspects of cultural resource management
- To develop and enhance a network of professional archaeologists and archaeological site managers for the purpose of transmitting theoretical and practical skills and encouraging high standards and best practices for (a) management of archaeological sites and resources, (b) archaeological research, and (c) aspects of cultural resource management
- To organize conferences and workshops, to produce publications, websites, and other mechanisms utilizing a variety of media to promulgate high standards and best practices for (a) management of archaeological sites and resources, (b) archaeological research, and (c) aspects of cultural resource management
- To provide the best qualified ICAHM Expert Members for desk audits and site visits to archaeological sites that have been nominated for inscription on the World Heritage List
- To provide the best qualified ICAHM Expert Members for monitoring of condition of archaeological sites that are inscribed on the World Heritage List
- To encourage the nomination of appropriate archaeological sites to the World Heritage List and to assist in nominations by contributing to comparative studies, giving advice about the preparation of nomination dossiers, management plans, or other relevant steps

In 2008, with the adoption of the Eger-Xi'an Principles, the role assigned to scientific committees in the work of ICOMOS was enlarged substantially. In response, ICAHM has greatly expanded membership, reinstituted international symposia, and has begun a publication series in collaboration with Springer Press, entitled *Multidisciplinary Studies in Archaeological Heritage Management*.

Before 2008, ICAHM had held two international symposia. The first was held in Stockholm from 12 to 16 December 1988, titled *Archaeology and Society: Large Scale Rescue Operations—Their Possibilities and Problems*. Edited by Gustaf Trotzig and Gunnel Vahlne, the papers were published in 1989 by the Nordic Secretariat of ICAHM. The second ICAHM symposium, *Archaeological Remains: In Situ Preservation*,

was held in Montreal from 11 to 15 October 1994. The papers were edited by Claire Mousseau and published in 1996 with support from the Ville de Montréal, Canadian Heritage, Hydro-Québec, and the Government of Québec.

In December of 2011, ICAHM held an international symposium in conjunction with the ICOMOS General Assembly Meeting in Paris, entitled *The Archaeology of Interdependence*. The papers are being published in the ICAHM publication series under that title. ICAHM sponsored the First International Conference on Best Practices in the Management of Archaeological World Heritage Sites in Menorca, Spain, in April of 2012. Selected papers from that conference are in press. The conference also produced the Menorca Statement, which promulgates ICAHM's intent to develop best practices for the management of archaeological sites and to refer to these when reviewing nominations of archaeological sites to the World Heritage List. The Statement also suggests that nomination dossiers include a plan, timetable, and estimated cost for developing adequate management capacity if this capacity is not fully in evidence. The nomination can then be used to generate necessary support for capacity building from a wide range of institutions beyond UNESCO.

Much of the concern about inadequate management capacity stems from damage at archaeological World Heritage Sites that results from a lack of visitor flow management and rapid site development. The first of four ICAHM Springer publications dealing with this was released in 2012, entitled *Tourism and Archaeological Heritage Management at Petra: Driver to Development or Destruction?* The subsequent three will examine this issue at Angkor, Machu Picchu, and Pompeii.

Mapping Archaeological Landscapes From Space: In Observance of the 40th Anniversary of the World Heritage Convention was published in the ICAHM/Springer series in 2013. ICAHM seeks to encourage nondestructive archaeological research methods and will nurture development and application of such technologies. It has cosponsored several training courses and workshops on these technologies in collaboration with NASA at the University of California, Berkeley; Johns Hopkins University; and Pontifical Catholic University of Peru, in Lima.

International Committee on Archaeological Heritage Management (ICAHM) (Conservation and Preservation), Fig. 1 ICAHM logo

ICAHM has been vocal on many issues since 2008 by means of press releases and letters to concerned parties. Among these are the looting of archaeological sites; the production of popular television shows that celebrate looting, such as the Spike TV series *American Diggers* and National Geographic series *Diggers*, enforcing international agreements that forbid or discourage the trade in looted artifacts; and the need to provide benefit to communities near archaeological sites as opposed to international hotel and restaurant chains.

Providing assistance to States Parties nominating or wishing to nominate archaeological sites to the World Heritage List is an important ICAHM program. ICAHM has provided assistance to specific sites, such as Poverty Point in the United States and the Jomon sites in Japan, and has begun an Africa Initiative that will work with States Parties in Africa to identify candidates for inscription.

ICAHM held an international conference in Cuzco, Peru, 27–30 November 2012, with the theme: *The UNESCO World Heritage Convention on its 40th Anniversary*. Over 100 papers were presented, and selected papers will be published in several volumes of the ICAHM Springer series (Fig. 1).

International Committee on Archaeological Heritage Management (ICAHM) (Cultural Heritage Management)

Ian Lilley
Aboriginal and Torres Strait Islander Studies Unit, University of Queensland, Brisbane, QLD, Australia

Basic Information

ICAHM is an International Scientific Committee (ISC) of ICOMOS. It was founded in 1987 at the 8th ICOMOS General Assembly in Washington, DC. The idea to develop such a body took a decade to bear fruit and was advanced by the UK's Henry Cleere and Sweden's Margareta Björnstad in particular. After ICAHM was established, key members drafted the *Charter for the Protection and Management of the Archaeological Heritage*, which was ratified in 1990 by the ninth ICOMOS General Assembly in Lausanne, Switzerland. Until 2008, the activities and membership of ICAHM were highly restricted by ICOMOS rules, as they were for all ISCs. In 2008, ICOMOS adopted the Eger-Xi'an principles for the International Scientific Committees. These principles dramatically freed up both membership eligibility and the range of activities the ISCs could pursue. ICAHM now has well over 200 members and is involved in initiatives in many parts of the world.

Major Impact

ICAHM was established to assist ICOMOS in advising the UNESCO World Heritage Committee on the management of archaeological heritage. This involves providing input to World Heritage Committee discussions concerning the inscription of archaeological resources on the World Heritage List, monitoring the physical condition of listed archaeological heritage and identifying listed properties that are in danger of being delisted because their condition has been allowed to deteriorate beyond acceptable limits. ICAHM's mandate also includes improving the management of all archaeological resources around the globe, whether or not they are World Heritage sites or even potentially eligible for listing. This is because the World Heritage Convention requires its signatories to help preserve the world's cultural and natural heritage, not just the sample of places that is on the World Heritage List.

ICAHM is especially concerned with the quality of work in archaeological heritage management in large projects in developing countries. For that reason, the committee not only continues to help develop standards and best practices but also discusses with various professional groups around the world ways in which professionalism can be advanced. On that basis, ICAHM collaborates with an array of international, regional, national, and local organizations that pursue related goals. ICAHM is unique among them in its focus on the development and propagation of effective and efficient *international* archaeological resource management standards and practices.

ICAHM's formal mandate covers three areas of activity: the management of archaeological sites and resources, archaeological research, and

aspects of cultural resource management. In these three connections, the committee's functions are to:

- Establish, promulgate, and encourage adherence to high standards and best practices
- Develop and enhance a network of professional archaeologists and archaeological site managers for the purpose of transmitting theoretical and practical skills and encouraging high standards and best practices
- Organize conferences and workshops, to produce publications, websites, and other mechanisms utilizing a variety of media to promulgate high standards and best practices
- Provide the best qualified ICAHM Expert Members for desk audits and site visits to archaeological sites that have been nominated for inscription on the World Heritage List
- Provide the best qualified ICAHM Expert Members for monitoring of condition of archaeological sites that are inscribed on the World Heritage List
- Encourage the nomination of appropriate archaeological sites to the World Heritage List
- Assist in nominations by contributing to comparative studies, giving advice about the preparation of nomination dossiers, management plans, or other relevant steps

There are four categories of membership. Experts include members selected by each national ICOMOS committee, who are voting members, as well as members of ICOMOS who have shown to the satisfaction of the ICAHM Executive Committee that they are competent in archaeological heritage management with a reasonable degree of professional experience, sufficient educational training, and, most importantly, a willingness to participate in ICAHM activities. Associates are members of ICOMOS who wish to build up their interest and expertise in the field of archaeological heritage management through participation in ICAHM activities. Institutional members are sought by the executive committee on a case-by-case basis. Affiliates are not members of ICOMOS but, in keeping with the Eger-Xi'an principles, are able to satisfy the executive committee that they would otherwise qualify as either an expert or associate. As encouraged by ICOMOS, the ICAHM executive is also creating a network of individual and institutional corresponding members who are engaged in relevant but not directly heritage-related activities.

ICAHM's *raison d'etre* is to advance heritage management in general by promoting *archaeological* heritage management in particular. This is an important role in a world often dominated by the interests of architecture and art history.

International Committee on the Underwater Cultural Heritage (ICUCH)

Thijs J. Maarleveld
Maritime Archaeology Programme, University of Southern Denmark, Esbjerg, Denmark

Basic Information

The International Committee on the Underwater Cultural Heritage (ICUCH) (http://icuch.icomos.org/) is the committee of the International Council on Monuments and Sites (ICOMOS) that addresses issues relating to the (international)

protection and management of underwater cultural heritage. As such it is both an ICOMOS International Scientific Committee and ICOMOS's taskforce for the 2001 UNESCO Convention on the Protection of the Underwater Cultural Heritage (2001). ICUCH has a global membership of professionals and has the mission to assist UNESCO in promoting the protection and sound ethical management of underwater cultural heritage. It focuses on international cooperation, legislative issues, and quality standards for interventions and training and closely cooperates with regional and topical NGOs in raising public awareness and counteracting the detrimental PR and activities of the treasure-hunting industry.

Major Impact

The International Committee on the Underwater Cultural Heritage (ICUCH) was established in 1991 with the specific purpose of defining minimum standards to which future dealings with the world's underwater cultural heritage should answer. The underwater world was rapidly opening up and being explored, both within and outside national jurisdictions. Many activities developed that would not befit archaeology or heritage management on land (Henderson 1993). Legal disputes had arisen, and although lawyers had addressed some of the issues and their possible solutions in organizations such as the International Law Association (ILA), they could not refer to a doctrinal text that could be supported by archaeologists and heritage professionals worldwide. Graeme Henderson, director of the Western Australian Maritime Museum, was commissioned by ICOMOS to find and invite the first 18 ICUCH members from 18 different countries around the world and agree their membership with their respective national committees. The working group thus formed prepared the text that was adopted at the 11th General Assembly of ICOMOS in Sofia, Bulgaria, in 1996 as the Charter for the Protection and Management of the Underwater Cultural Heritage. Since then, the Sofia Charter has had significant impact.

In 1997, UNESCO's General Conference decided that a binding legal instrument should be elaborated to find consistency in approaches toward the underwater cultural heritage. In the meantime, the original group of 18 ICUCH members had been refreshed through elections and extended to 24. Under its second president, Robert Grenier, ICUCH assisted at the complicated negotiations, through which such a binding legal instrument was elaborated for UNESCO. In 2001 this led to the adoption of the Convention on the Protection of the Underwater Cultural Heritage into which the principles of the Sofia Charter have been incorporated. The Convention entered into force in January 2009. ICUCH is committed to help in its promotion and implementation and is a statutory advisor to the Scientific and Technical Advisory Board that was established by the meeting of States Parties to the Convention. The number of States Parties is gradually rising and is presently around 60 (status July 2018).

In conjunction with the UNESCO secretariat, ICUCH has elaborated the UNESCO Manual for Activities directed at Underwater Cultural Heritage that was published in English, Spanish, and French in 2013, in Chinese and Italian in 2014, and in Arab in 2016 (Maarleveld et al. 2013).

In 2009, ICUCH saw a major restructuring. New statutes were adopted and a wider membership is envisaged. Nevertheless, ICUCH membership is not as open to all ICOMOS members as membership to other ICOMOS International Scientific Committees. The reason for this is as unfortunate as it is real: people with connections to treasure hunting in maritime archaeology aspire to enhance their credibility by membership of a committee such as ICUCH, and as such, membership must be controlled. An intricate ballot system is therefore in place which among other things requires public and recognized adherence to the 1996 Charter. Among other things this implies standing free from involvement in or promotion of funding of activities through the sale of artifacts. Decisions on membership are made by the Bureau. Besides high professional standards, the basis for ICUCH's credibility as a global organization is regional representation. The Bureau has nine members, with the proviso that these include at least one member from each of the five UNESCO regions. Three of the nine bureau posts are up for election every year. As the number

of well-qualified professionals in underwater archaeology and heritage management is still limited, some regional distortion in the general membership nevertheless occurs. The priority in accepting new members lies with underrepresented regions and non-represented states, especially states that have ratified the 2001 Convention.

ICUCH is a formal advisor to the Scientific and Technical Advisory Body of the Meeting of States Parties of the 2001 Convention and assists the UNESCO secretariat in regional meetings and in training programs. The establishment of curricula and handbooks and operating as a clearinghouse for information and quality control is a role it can play thanks to close cooperation with topical and regional organizations such as the International Congress of Maritime Museums (ICMM), the Nautical Archaeology Society (NAS), the Advisory Council on Underwater Archaeology (ACUA), the Society for Historical Archaeology (SHA), the Australasian Institute for Maritime Archaeology (AIMA), the UK-based Joint Nautical Archaeology Policy Committee (JNAPC), and many others. Publications for which ICUCH's input has been crucial include a Heritage at Risk volume (Grenier et al. 2006) and a Training Manual for the UNESCO Foundation Course on the Protection and Management of Underwater Cultural Heritage in Asia and the Pacific (Manders and Underwood 2012).

How International Conventions and Charters Have Influenced Archaeology Interpretation and Presentation

To a large extent, the drawing up of new charters and conventions is the result of the extension of the concept of heritage. What sometimes appears to be

a proliferation may simply be a reflection of new realities that are more varied and complex. —Jean-Louis Luxen (2004)

Introduction

The public interpretation and presentation of archaeological heritage has become an essential component in the conservation and protection of cultural heritage values and sites. We can trace the conceptual roots of modern guidelines for public interpretation and presentation of archaeological heritage back to the late nineteenth century (Getty Conservation Institute 2015). By the early twenty-first century, the mechanisms and processes of public interpretation had reached a heightened level of sophistication and effectiveness. In the international arena, several leading organizations emerged that carry the banner of interpretation principles for access, inclusion, and respect for multiple points of view. These principles emphasize the importance of community engagement and participation in all phases of program planning, development, and delivery. Conventions and charters have been two of the most commonly used categories of international documents to frame standards and guidelines for archaeological heritage management and presentation. However, international documents that specifically addressed the presentation and interpretation of archaeological heritage did not take shape until the late twentieth century.

Conservation and Protection Through Public Presentation

The 1930s was the beginning of an expansion of the concepts of heritage, and heritage conservation has lasted to the present day; an evolving list of international documents, conventions, and charters has led to more recent discussions and debates about resource significance. Concerns for relevancy, community engagement, inclusion, and power sharing led to calls for the promulgation of principles of interpretation and presentation that go beyond a recitation of facts. Our standards today call for effective interpretation approaches that facilitate opportunities for people to form tangible and intangible links to resource meanings, values, and attributes of authenticity. Going beyond a recitation of facts, modern interpretation and presentation programs seek to connect resource meanings to audience experiences, demonstrate relevancy, and promote public stewardship.

As a specialty within the sphere of public archaeology and cultural heritage management, the public interpretation of archaeological and cultural sites has become an essential component in the conservation and protection of cultural heritage values and sites. Beginning in the 1960s and 1970s in the United States, and developing later in other parts of the world, legal frameworks emerged to identify and protect cultural heritage assets. The resultant rapid accumulations of archaeological and historical site information and artifact assemblages led to heightened public and professional awareness and concern for protection and preservation. In the face of an increasing public interest and demand for information, archaeologists and their cultural heritage colleagues began to more actively collaborate to devise the effective strategies for public presentation and interpretation. Until the 1990s, publications on public presentation and interpretation strategies and standards were rare and largely relegated to isolated accounts and academic gray literature.

However, by the latter part of the twentieth century, many archaeologists were addressing the contemporary context of their research as part of a growing practical and ethical awareness. The 1990s saw the emergence of greater energy and funding devoted to the public interface of archaeology as the professional community realized that intellectual introversion was no longer acceptable and that more attention should be paid to the mechanisms, programs, and standards of public interpretation and presentation. Inspired by visionaries such as Freeman Tilden (1957), interpretation practitioners increasingly rejected programs and presentations that did not attempt to go beyond a recitation of facts. Only programs that facilitated and provoked emotional and

intellectual connections of the audience to meanings inherent in the resource were deemed acceptable (Jameson and Baugher 2007).

By the early twenty-first century, the mechanisms and processes of public interpretation had reached a heightened level of sophistication and effectiveness. In North America, the US National Park Service (NPS) and the National Association of Interpretation (NAI) took the lead in standards development. NPS, through its Interpretive Development Program (IDP), promulgated a multifaceted, delivery mode specific, employee training program (Jameson 1997, 2007). NAI, a nongovernmental and nonprofit, independent organization, provides a number of training and certification opportunities and is a major advocacy group for standards development among both government and nongovernment organizations and agencies. The NAI annual Interpreters Workshop and International Conference are major conference events among professional interpreters.

The evolving philosophies of NPS, NAI, and similar advocacy groups have emphasized that, at historic sites, monuments, and parks, the process of effective interpretation allows each visitor to find an opportunity to personally connect with a resource or place. Each individual may connect to the place in a different way, and some may not connect immediately, but everyone should have an opportunity to explore how that special site or place is meaningful to him or her. The goal of interpretation, then, is to increase each visitor's enjoyment and understanding of the site, monument, or park and to allow visitors to care about the parks on their own terms. Many have argued that such personal connections are crucial in gaining public support for conservation.

In the international arena, leading organizations have emerged that are carrying the banner of interpretation principles for access, inclusion, and respect for multiple points of view. The NAI International Conference, held annually in different parts of the world, promotes international partnerships and instigation of interpretative facilities to enhance tourism experiences, benefit local economies, and sustain sensitive interpretation of heritage resources. Interpret Europe, an independent organization established in 2010, espouses similar best practice principles in making interpretive programs locally relevant and sensitive to differences of culture, age, and gender and in organizing complex networks and maintaining a database of best practices (Interpret Europe 2019). National organizations such as Interpretation Australia have been leaders in establishing communication networks and online access to information on best practices guidelines and case studies.

The International Council on Monuments and Sites (ICOMOS) is a global nongovernmental organization associated with UNESCO. ICOMOS charters compliment UNESCO Conventions in providing context and protection guidelines for cultural heritage (ICOMOS n.d.). Its creation in 1965 is the logical outcome of the first interviews that architects, historians, and international experts began early in the twentieth century and that materialized in the adoption of the Charter of Venice in 1964. Its mission is to promote the conservation, protection, use, and enhancement of cultural heritage monuments, building complexes, and sites. Through numerous charters, studies, conferences, symposia, and discussions since 1965, ICOMOS has gradually evolved a more holistic philosophy of cultural heritage protection and interpretation.

ICOMOS works for the conservation and protection of cultural heritage places and is the only global nongovernment organization of its kind. ICOMOS boasts a network of over 10,000-member interdisciplinary experts such as architects, historians, archaeologists, art historians, geographers, anthropologists, engineers, and urban planners. ICOMOS expert members participate in the development of doctrine, evolution and distribution of ideas, and advocacy.

As the Advisory Body of the World Heritage Committee for the implementation of the World Heritage Convention of UNESCO, ICOMOS reviews nominations for World Heritage Site status and ensures the conservation status of properties. Through its national committees and international scientific committees (ISCs), ICOMOS provides leadership and example for

best practice in cultural heritage conservation and presentation (ICOMOS 2018).

Terminology and Categories of International Documents

For the uninitiated, and even for the more experienced, the vast labyrinth of international heritage conservation documents can be daunting to comprehend. To provide clarity of terminology, some definitions and explanations are warranted.

Created within sources of legal authority, "conventions" and "recommendations" derive from intergovernmental organizations such as UNESCO, the Council of Europe, and other governmental and international agencies. Once conventions are signed and ratified, they are binding for the member states. "Recommendations," though not binding in terms of force of law, can nevertheless represent highly recommended management guidelines of public authorities and other stakeholders. "Conventions" and "recommendations" are invariably subjected to meticulous preparations and comprehensive consultations between states to ensure the widest possible consensus (Luxen 2004).

"Charters," "principles," and "codes of ethics," on the other hand, represent moral rather than legal authority. These documents commonly establish principles, definitions, and codes of conduct that professionals and specialists set for themselves as guidelines for best practice. This self-regulatory, collective approach provides flexibility and adaptability to change. To acquire strong moral credibility, these norms need to be the outcome of very broad consultations involving as many professionals as possible from all regions of the world (Luxen 2004).

An inducing relationship has sometimes developed between charters and conventions and other documents of varying origins and scopes. Commonly, later documents and charters have built on, expanded, and been inspired by earlier documents of related themes. For example, the ICOMOS Venice Charter (1964) codified internationally accepted standards of conservation, and precipitated, with expanded definitions of concepts such as "heritage" and "authenticity," the UNESCO World Heritage Convention (1972) and the ICOMOS NARA Document on Authenticity of 1994 (Taylor 2004). Another example is the ICOMOS Charter on Underwater Cultural Heritage (1996) that precipitated UNESCO's Convention on the Protection of Underwater Cultural Heritage (2001). All these categories of documents form a considerable corpus of norms that complement national and regional legislative mandates in each country.

History of International Conventions and Charters Related to Cultural Heritage Conservation

To understand the advance of archaeological heritage interpretation and presentation standards and guidelines, it is useful to review the historical development of documents and philosophies that reflect incrementally expanding concepts and definitions of cultural and archaeological heritage, its components, meanings, and attributed values (Getty Conservation Institute 2015). Historically, beginning in the nineteenth century, there are a great number of international conventions, charters, policies, and recommendation documents that have addressed the treatment and protection of archaeological objects and information. The Principals of the Society for the Protection of Ancient Buildings as Set Forth upon its Foundation (The SPAB Manifesto) of 1877 championed preservation of original fabric versus poorly conceived restorations. The Recommendations of the Madrid Conference (1904) emphasize the importance of minimal intervention in dealing with ruined structures and of finding a functional use for historic buildings or adaptive reuse in modern parlance. Both documents addressed preservation of architectural remains.

The Charter of Athens (1933), significant in that it advanced concepts that are today referenced as elements of "intangible heritage," promoted the preservation of urban architectural heritage and defined the built heritage as possessing spiritual, cultural, and economic values.

The Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954) echoed international sentiments following World War II to prevent theft and vandalism of cultural institutions and property (not just buildings) during armed conflicts. It established an "International Register of Cultural Property under Special Protection." The UNESCO "Recommendation on International Principles Applicable to Archaeological Excavation" (1956) called for states to create a licensing or monitoring authority to document activities and finds. Significantly for this discussion of the development of presentation and interpretation guidelines, it also called for states to undertake educational efforts to promote respect for remains of the past.

The ICOMOS Venice Charter, "International Charter for the Conservation and Restoration of Monuments and Sites" (1964), is important in that it codifies internationally accepted standards of conservation practice relating to architecture and sites. It sets forth principles of conservation based on the concept of authenticity and the importance of maintaining the historical and physical context of a site or building. The Venice Charter states that monuments are to be conserved not only as works of art but also as historical evidence. It also sets down the principles of preservation, which relate to restoration of buildings with work from different periods. The Venice Charter, together with the UNESCO World Heritage Convention of 1972, continues to be a crucially influential international conservation document.

Council of Europe's "European Convention on the Protection of the Archaeological Heritage" (1969) calls for the application of scientific methods to archaeological research and an end to illegal excavations as two important principles for safeguarding archaeological heritage. It makes several recommendations, including the creation of "reserve zones" for preservation of evidence to be excavated at a later time, preparation of inventories of publicly and privately held archaeological objects, and exchange of these materials where possible for scientific and educational purposes.

The UNESCO "Convention Concerning the Protection of the World Cultural and Natural Heritage" (World Heritage Convention), adopted in 1972, promotes an international perspective on cultural heritage by inviting member states to submit an inventory of properties forming its national cultural and natural heritage to be included in a list of World Heritage sites. The convention encourages national efforts at protecting cultural and natural heritage and promotes international recognition and cooperation in safeguarding worldwide heritage sites. The Operational Guidelines for the Implementation of the World Heritage Convention outline the criteria to be met by sites on the World Heritage List.

In 1990, inspired by the success of the Venice Charter, the ICOMOS International Committee on Archaeological Heritage Management (ICAHM) created the "Charter for the Protection and Management of the Archaeological Heritage." The charter was created in response to the increasing threats to archaeological sites worldwide from looting and land development. The Charter attempts to establish principles and guidelines of archaeological heritage management that are globally valid and can be adapted to national policies and conditions. It lays out general principles for investigation, maintenance, and conservation as well as architectural reconstruction. It also notes the importance of high academic and professional standards in relevant fields of expertise and the need for international cooperation.

The Promulgation of International Presentation and Interpretation Guidelines

International documents that specifically addressed the presentation and interpretation of archaeological heritage did not take shape until the late twentieth century. The ICOMOS Charter on Cultural Tourism of 1999 encouraged the development of measurable goals and strategies relating to the presentation and interpretation in the context of their preservation and conservation.

The ICOMOS Australia National Committee's Charter for the Conservation of Places of

Cultural Significance (The Burra Charter), first issued in 1979 and revised significantly in 1999 and 2013, is a national charter that establishes principles for the management and conservation of cultural sites in Australia. The Charter is particularly significant for its definition of cultural significance and the standards it outlines for using cultural significance to manage and conserve cultural sites. It provides an example of how international principles can be adapted to the values and needs of a nation or cultural groups within that nation. Significantly, it contains a definition of interpretation (Article 1.17): "Interpretation means all the ways of presenting the cultural significance of a place," with an explanatory note: "Interpretation may be a combination of the treatment of the fabric (e.g., maintenance, restoration, reconstruction); the use of and activities at the place; and the use of introduced explanatory material." Article 24.1, "Retaining associations and meanings," states that "Significant associations between people and a place should be respected, retained and not obscured. Opportunities for the interpretation, commemoration and celebration of these associations should be investigated and implemented." Article 24.2 states that "Significant meanings, including spiritual values, of a place should be respected." Article 25, "Interpretation," states, "The cultural significance of many places is not readily apparent and should be explained by interpretation. Interpretation should enhance understanding and enjoyment and be culturally appropriate."

The Council of Europe's Convention on the Value of Cultural Heritage for Society (Faro Convention of 2005) went into effect in 2011. It expands on the notions of heritage protection and conservation to pose the questions of why, and for whom, the heritage values are transmitted. Drawing on the United Nations' "Universal Declaration of Human Rights," it promotes the idea that knowledge and use of heritage are part of a citizen's right to participate in cultural life. The text presents heritage both as a resource for human development, the enhancement of cultural diversity, and the promotion of intercultural dialogue and as part of an economic development model based on the principles of sustainable resource use (Council of Europe 2012).

The ICOMOS Charter on Interpretation and Presentation of Cultural Heritage Sites (2008)

Unquestionably, the most important international document to date relating to interpretation and presentation of archaeological heritage sites is the 2008 "ICOMOS Charter on the Interpretation and Presentation of Cultural Heritage Sites," sometimes referred to as the "Ename Charter," referring to the place in Belgium where the first drafts of the charter were prepared. Largely avoiding the questions of the "how and when" of interpretation, as emphasized by NPS and NAI, the Charter lays out seven principles, or key ingredients, of interpretation and presentation in reference to the conservation, education, and stewardship messages that represent the transcendent humanistic values of the resource. The seven basic principles for interpretation provide an outline of professional and ethical standards. The principles place emphasis on the essential roles of public communication and education in heritage preservation and are presented under the following basic headings: Access and Understanding; Information Sources; Context and Setting; Authenticity; Sustainability; Inclusiveness; and Research, Education, and Training.

On the surface, the principles are generally commonsensical in terms of conditions and prescriptions for effective public interpretation. Just how the principles are articulated at local settings, however, will determine how well they are received in international circles and whether they are considered desirable, practical, and feasible. In countries with little or no tradition of multiculturalism, poor human rights histories, and poorly developed infrastructure, practical applications of the Charter are especially challenging (Jameson 2008).

The Ename Charter, to avoid appearances of being overly prescriptive and culturally or linguistically biased, does not address methodology, or the content of interpretive messages, or

suggest philosophical approaches other than those implied by the Principles. Rather, it attempts to consciously avoid interpretive content descriptions, specific narratives, or educational and technological constructs. Originally drafted and promoted by the Ename Center for Public Archaeology and Presentation in Belgium, and subsequently revised under the auspices of the ICOMOS International Committee on Interpretation and Presentation of Cultural Heritage Sites (ICIP), the Charter continues to be scrutinized by the international community of interpretation experts.

The ICIP, in addition to promoting the development, adoption, and application of the Charter principles, studies the evolving techniques and technologies of public interpretation and presentation, evaluating their potential to enrich contemporary historical discourse and to heighten sensitivity to the universal values and particular modes of human expression embodied in cultural heritage sites. The work of the committee explicitly focuses on the experiential dimension of visits to cultural heritage sites, particularly by means of various media and methods of public communication (ICIP 2015). The business of formulating best practices in interpretation and presentation at a cultural setting, country, or institution is one of the chief activities of ICIP- sponsored events. The sessions, seminars, and workshops organized by ICIP members, in association with interdisciplinary colleagues, serve as experiments in formulating best practices (Silberman 2009: 7–8).

Conclusions

With conceptual roots going back to first half of the twentieth century, the public interpretation and presentation of cultural heritage sites has become an essential component in the conservation and protection of cultural heritage values and sites. By the early twenty-first century, the mechanisms and processes of public interpretation had reached a heightened level of sophistication and effectiveness. In the international arena, a number of leading organizations have emerged that are carrying the banner of interpretation principles for access, inclusion, and respect for multiple points of view. These principles emphasize the importance of community engagement and participation in all phases of program planning, development, and delivery.

Conventions and charters have been two of the most commonly used categories of international documents to frame standards and guidelines for archaeological heritage management and presentation. Not until the late twentieth century did international documents that specifically addressed the presentation and interpretation of archaeological heritage come into being.

The 1930s was the beginning of an expansion of the concepts of heritage and heritage conservation has lasted to the present day; an evolving list of international documents, conventions, and charters has led to more recent discussions and debates about resource significance. Later in the century and into the twenty-first century, concerns for relevancy, community engagement, inclusion, and power sharing led to calls for the promulgation of principles of interpretation and presentation that go beyond a recitation of facts.

The most important international document to date relating to interpretation and presentation of archaeological heritage sites is the ICOMOS Charter on the Interpretation and Presentation of Cultural Heritage Sites (2008). The Charter lays out seven principles of interpretation and presentation in reference to the conservation, education, and stewardship messages that represent the transcendent humanistic values of the resource. These principles provide an outline of professional and ethical standards, placing emphasis on the essential roles of public communication and education in heritage preservation. Future articulation and implementation of the principles will be characterized by site, program, and cultural nuances so that strategies that are effective in on area or country may not be as viable in another.

In the West, we must remind ourselves that most of these interactions occur in countries from the Western cultural tradition and stem

from the predominately Western ideas of equal treatment, ethnic sensitivity, and accountability for multiple points of view that are constantly and openly debated. Many of the categories used in international charters and documents, such as world heritage site, national park, and national monument, are notions of commemoration originating in the West. As we enter discussions of international and universal relevance, we need to be cautious in avoiding terminology that can appear, to a non-Westerner, to be patronizing and insensitive. Some of the terminology used in these documents may not always have relevancy in areas outside the Western cultural tradition. Multiculturalism may be rejected altogether as invalid or undesirable by some cultures and countries, making preconditions for inclusive heritage interpretation and presentation more challenging.

International Conventions Pertaining to Heritage Policy: Introduction

Ricardo J. Elia
Department of Archaeology, Boston University, Boston, MA, USA

Introduction

Efforts to develop policies for the protection of cultural heritage at the international level are dominated by six major conventions that have entered into force during the half century between 1956 and 2006. Each convention is dedicated to protecting cultural heritage either of specific types or under specific conditions: heritage at risk during armed conflict (1954 Hague Convention); cultural objects threatened by theft, looting, and other illicit movement (1970 UNESCO Convention, 1995 UNIDROIT Convention); cultural and natural sites of "outstanding universal value" (1972 World Heritage Convention); underwater cultural heritage (2001 Underwater Convention); and intangible heritage (2003 Intangible Heritage Convention). All of these treaties were adopted under the auspices of UNESCO, the United Nations Educational, Scientific and Cultural Organization, with the exception of the 1995 UNIDROIT Convention, which was developed at the request of UNESCO by UNIDROIT, the International Institute for the Unification of Private Law. (For texts of the conventions and related commentary, see Prott and O'Keefe (2010) and the website of the UNESCO's Culture Sector (UNESCO n.d.)).

In international law, conventions are treaties, legal agreements between nations that give their consent to be mutually bound. The process of developing a convention that is approved by multiple states is normally a lengthy and challenging enterprise that follows a specific framework within international law, including procedures and terminology that may be baffling to a non-specialist (Forrest 2010: 32–56). Nations that ratify conventions are known as *States Parties*. *Signature* and *ratification* of a convention are not necessarily the same thing: in some treaties, like the 1954 Hague Convention and its protocols, signature means approval of the adopted text, an intention to move towards ratification, and a pledge not to thwart the goals of the convention pending ratification. So, for example, both the United States and the United Kingdom signed the convention on armed conflict in 1954; however, the United States did not ratify it until 2009, and the United Kingdom has yet to ratify it, although it has declared its intention to do so. In the remaining UNESCO cultural heritage conventions, signature was not required at the time of adoption of the convention text. In all cases, *ratification* signals a nation's formal agreement to be bound and is evidenced by the deposit of *instruments of ratification*. In addition to ratification, the terms *accession*, *acceptance*, and *approval* may also be used to signify a state's agreement to be bound to the terms of a convention; there may be slight differences of meaning among these terms from convention to convention, but in the end, they all denote ratification.

When States Parties deposit their instruments of ratification, they may (unless specifically prohibited by the terms of the convention itself) make unilateral declarations that limit, qualify, or interpret certain aspects of the convention. These

reservations sometimes have a profound effect on the implementation of the treaty. For example, when the United States announced its "acceptance" of the 1970 UNESCO Convention on the illicit movement of cultural property, it published one reservation and six "understandings" (O'Keefe 2000: 106–109). These statements were considered to qualify the US acceptance of the convention so drastically that some have questioned whether it has even implemented the convention (Prott and O'Keefe 1989: 794–796).

International conventions do not go into effect, that is, are not binding on assenting nations until a specified number of States Parties have ratified. *Entry into force* is specified in the text of each convention. For example, the 1954 Hague Convention on armed conflict entered into force in 1956, 3 months after the ratification of the convention by the fifth state. The Intangible Heritage Convention was adopted in 2003 and entered into force in 2006, 3 months after the ratification by the 13th nation.

Although the six cultural heritage conventions constitute an impressive body of international law, they do not comprise a comprehensive or coherent system of either heritage protection or policy. Each was developed in response to particular concerns during a specific period of recent history. Given the multiplicity of national legal systems, interests, and perspectives that were involved during the creation of the various conventions, it is not surprising that there is no unitary vision of what cultural heritage is or how it should be protected. Even the terminology relating to what we term "cultural heritage" differs from convention to convention and reflects evolving perspectives on the notion of tangible and intangible heritage. For example, both the 1954 Hague Convention and 1970 UNESCO Convention use "cultural property," but in the earlier treaty, the term refers to "movable or immovable property of great importance to the cultural heritage of every people" (Article 1), while the later convention defines the same term in a more nationalistic sense as "property which, on religious or secular grounds, is specifically designated by each State as being of importance. . ." (Article 1). The 1972 World Heritage Convention and the 2001 Underwater Convention both use "cultural heritage," while the 1995 UNIDROIT Convention prefers "cultural objects."

Key Issues/Current Debates/Future Directions/Examples

Armed Conflict

The earliest of the cultural heritage conventions also has the deepest roots. The 1954 Hague *Convention for the Protection of Cultural Property in the Event of Armed Conflict*, along with the simultaneously adopted *Protocol to the Convention for the Protection of Cultural Property in the Event of Armed Conflict* (now known as the First Protocol), sought to prevent a repetition of the unprecedented destruction, plunder, and vandalism of cultural sites and objects during the Second World War. But its antecedents reach back to the eighteenth century, when an evolving customary law of war among European nations recognized the importance of protecting cultural sites from destruction and cultural objects from looting. Despite the excesses of state-sanctioned cultural plunder by Napoleon's armies, and indeed partly because of them, the notion that cultural heritage should be respected and immune from plunder achieved normative status among Western armies during the nineteenth century. In the Annex to the 1907 Hague *Convention IV Respecting the Laws and Customs of War on Land*, a revision of an 1899 convention, all pillage was outlawed and special provisions were included to spare cultural sites, including historic monuments, during sieges and bombardments. Both attackers and defenders had duties in this regard: the attackers were obliged to take "all necessary steps. . . as far as possible" to spare cultural sites, while the defenders were required to identify cultural sites with "distinctive and visible signs," give notice of their locations beforehand, and refrain from using them for military purposes (O'Keefe 2006: 22–34).

Building on these dual obligations – that of both attacker and defender – the 1954 Hague Convention attempts to strengthen protection of both movable and immovable cultural property (using the term employed in the convention) by promoting the safeguarding of, and respect for, cultural property (O'Keefe 2006: 92–201; Forrest 2010: 78–108). Safeguarding means that nations prepare in times of peace for the possible effects of war on cultural property in their countries. Respect means both refraining from use of cultural property for purposes that might expose it to damage or destruction during wartime and refraining from any act of hostility towards cultural property. These measures to protect cultural property, however, are liable to be waived for the sake of imperative military necessity. In addition, States Parties agree to prevent theft, pillage, misappropriation, or vandalism of cultural property as well as reprisals against the same and to cooperate with local authorities to protect cultural property during occupation of the territory of another states party. The convention also allows for the granting of "special protection" – the designation of refuges or shelters for certain movable or immovable cultural property.

One of the anachronistic features of the 1954 Hague Convention is the notion that cultural property may be designated with a "distinctive marking" – the now familiar "Blue Shield" emblem. Officials responsible for the protection of cultural sites and objects may also wear the emblem. The notion of marking cultural sites in wartime goes back to the nineteenth century, but in the modern age of remote, long-distance bombardment when even ground forces may not be in direct visible contact with targets, the effectiveness of such markings for protecting cultural sites is problematic. In addition, the changing nature of warfare itself – characterized in recent decades by insurgencies, guerilla operations, and terrorist actions, all of which employ asymmetric methods of conflict – has rendered the very concept of identifying one's important cultural sites to one's enemy problematic. Despite its often horrific violence, the nineteenth-century warfare among "civilized" nations was pursued by standing armies led by generals who often communicated with one another and shared a common interest in certain civilities, including the protection of churches, museums, and monuments. In recent conflicts, cultural sites have sometimes been deliberately targeted for ideological reasons, so that advance notification of their location may actually invite attack. Some belligerents have also deliberately used cultural sites for military purposes precisely because they are counting on their first-world foes to refrain from attacking such sites.

Recent conflicts in Iraq during the First Gulf War (1991) and in the Balkans during the 1990s highlighted several inadequacies in the protective regime envisioned by the 1954 convention and led to the adoption in 1999 of the *Second Protocol to the Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict* (O'Keefe 2006: 236–301; Forrest 2010: 110–237). The Second Protocol attempts to restrict the circumstances when military necessity may override the protection of cultural property; emphasizes the principle of proportionality in military actions that may affect cultural property; provides for new system of "enhanced protection"; strengthens the protection of cultural property during occupation; and provides for criminal enforcement of violations. Despite these efforts, the problems evidenced in the Second Gulf War – including looting of the Iraq Museums and other institutions, the plunder of archaeological sites, and the use of cultural sites for military purposes (Elia 2008) – demonstrates that we are far from achieving success in this area (see also Renfrew and Farchakh-Bajjaly, this volume).

Illicit Traffic

Two cultural heritage conventions attempt to deal in tandem with the problem of the illicit movement of cultural heritage through theft, looting, illegal export, and illicit transfer. As early as 1960, archaeologically rich countries such as Mexico and Peru were petitioning UNESCO to develop an international agreement that might stem the flow of illicit cultural materials out of their countries and into developed, art-market nations like the United States and United Kingdom. The result, adopted in 1970, was the UNESCO *Convention on the Means of Prohibiting and*

Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (Prott and O'Keefe 1989: 726–801; O'Keefe 2000; Forrest 2010: 166–196). This celebrated and influential convention was an imperfect instrument, and, in 1984, UNESCO asked UNIDROIT, the International Institute for the Unification of Private Law, to develop another treaty to address some of the inconsistencies and omissions of the 1970 convention. In 1995, the UNIDROIT *Convention on Stolen or Illegally Exported Cultural Objects* was adopted and entered into force in 1998 (Prott 1997; Forrest 2010: 196–223).

The 1970 UNESCO Convention identified the illicit movement of cultural property as "one of the main causes of the impoverishment of the cultural heritage of the countries of origin" (Article 2). In early drafts, a relatively straightforward scheme of international cooperation in the area of export and import controls was envisioned. Exporting countries were required to introduce a certificate to accompany the legal export of cultural property and to prohibit the exportation of cultural property unless accompanied by a certificate. This provision survived in Article 6 of the convention, but its companion piece – a requirement that importing countries recognize the export certificates of States Parties and prohibit import of cultural property without them – was removed from the final text, largely by the efforts of the United States, eager to protect the free-trade practices of its thriving art trade, including dealers, private collectors, and museums (O'Keefe 2000: 57). In its place was substituted a highly restrictive set of rules that only required nations to take necessary measures, "consistent with national legislation," to prevent museums from acquiring illegally exported cultural property; in addition, States Parties were required to prevent the import of cultural property stolen from a museum or institution in another State Party if properly documented or inventoried (Article 7).

Another provision of the 1970 convention allows a State Party "whose cultural patrimony is in jeopardy from pillage of archaeological or ethnological materials" (Article 9) to request assistance from other states and to help control the export and import of specific materials if warranted. This highly restrictive approach to addressing the global problem of archaeological site looting ensured that a steady stream of plundered, undocumented archaeological material would continue to flow into the antiquities market, largely unimpeded by the 1970 convention. Thus, although the compromise text of 1970 was accepted because it was considered essential to have the support of at least one major art-importing nation (i.e., the United States, which ultimately ratified the convention in 1983), there is no doubt that the overall effectiveness of the 1970 regime was thereby seriously diminished. While some importing countries, such as Australia (O'Keefe 2000: 102–106), interpreted the 1970 convention in a broad sense – effectively agreeing to follow the export rules of other States Parties – most art-market states that have ratified the convention in recent years, including the United Kingdom, Switzerland, and Japan, have followed the narrow interpretation of the convention favored by the United States, by requiring States Parties to make formal requests for assistance, which may take the form of bilateral agreements that restrict the import of specific categories of cultural objects. Currently, the United States has 13 bilateral agreements made under Article 9 of the 1970 convention.

The 1995 UNIDROIT Convention is complementary to the 1970 UNESCO Convention and addresses several important issues that were not adequately covered in the earlier treaty, including the ability of private owners to seek the return of stolen or illegally exported cultural objects (the 1970 convention is a public-law treaty, requiring state-to-state relations); rules relating to protection of bona fide, third-party purchasers; and the appropriateness of payment of compensation to them. UNIDROIT's effort was complicated by the need to harmonize fundamental differences in the traditional practices of civil law systems and common law systems. Common Law jurisdictions generally do not allow thieves or third-party purchasers to obtain good title to stolen objects nor do they favor the payment of compensation to good-faith purchasers. In civil law systems, however, bona fide purchasers may obtain good title after a specified period of time or, if they must return a

stolen object to an original owner, may be entitled to compensation. The 1995 UNIDROIT Convention attempts to resolve this quandary through compromise. On the one hand, it enunciates the Common Law principle that "the possessor of a cultural object which has been stolen shall return it" (Article 3(1)); on the other hand, it also adopts the civil law notion that bona fide purchasers are entitled to reasonable compensation if they exercised "due diligence" in acquiring an object (Articles 4(1) and 6(1)). The convention also sets time limits within which claimants may seek the return of stolen cultural objects.

The UNIDROIT Convention distinguishes between two categories of cultural objects and creates different rules for their return. First are "stolen cultural objects," which include archaeological materials that have been illegally excavated or legally excavated but illegally retained, in accordance with the law of the state where the objects were found. Including the products of illegal excavations in the category of stolen cultural objects is significant and contrary to the views of free-market proponents, who generally distinguish between an inventoried object stolen from a museum and the products of clandestine excavations that are classified as merely "illegally exported." The second category of cultural objects in the convention is "illegally exported cultural objects," which must be returned to a requesting state if their removal significantly impairs the physical condition or context of the object; the integrity of a complex object; the preservation of information; or the traditional or ritual use of the object by a tribal or indigenous community.

Also significant is the convention's articulation of the elements of "due diligence" – the reasonable efforts made by the possessor of a stolen cultural object at the time of acquisition. Absent due diligence, the possessor is not entitled to reasonable compensation for the return of the object.

Considered together, the 1970 UNESCO and 1995 UNIDROIT conventions may seem to be exclusively concerned with efforts to ensure the return, restitution, and repatriation of illicitly removed cultural objects. Indeed, these are important issues in the two conventions, but one should not lose sight of their fundamental purpose: to prohibit and prevent (both verbs are present in the title of the 1970 convention) the behavior that results in the illicit movement of cultural objects. Their primary goal, therefore, is not to return illicitly removed cultural objects but to prevent their removal in the first place. Although the 1970 convention has serious flaws, it has dominated discussions about cultural heritage since its adoption and is a milestone in the evolution of museum acquisition policies. And the UNIDROIT Convention, for all the opposition it has engendered from pro-market forces, has forced collectors and dealers to address explicitly their behavior relating to due diligence and investigations of provenance.

World Heritage

The 1972 UNESCO *Convention Concerning the Protection of the World Cultural and Natural Heritage* aims to protect cultural and natural sites of global importance as the common heritage of humanity (Francioni 2008; Forrest 2010: 224–286). It creates a system to promote international cooperation to assist nations to identify, protect, and manage sites of "outstanding universal importance" in the face of increasing threats from decay as well as social and economic conditions. The World Heritage Convention enjoys the widest participation of all the cultural heritage conventions, with 188 States Parties as of November 2011 (World Heritage n.d.).

Central to the World Heritage Convention is the World Heritage List, an inventory of the world's most important cultural and natural sites, which enjoys broad support and recognition throughout the world. States Parties wishing to nominate sites for the list must demonstrate that they have taken effective measures to ensure their protection, conservation, and management. An intergovernmental Committee for the Protection of the World Cultural and Natural Heritage considers nominations and decides whether or not to inscribe nominated sites on the World Heritage List; it also acts on requests for international assistance, including financial assistance. Currently, there are 936 sites inscribed on the list, including 725 cultural, 183 natural, and

23 mixed located in 153 countries (World Heritage n.d.). The Committee also maintains a List of World Heritage in Danger, which consists of properties on the World Heritage List that are determined to be a serious risk of damage or destruction. Currently, there are 35 sites on the list in danger (World Heritage n.d.).

The World Heritage Convention is more than a commemorative list of globally significant sites. Its emphasis on heritage rather than property, on immovable sites rather than movable, and on its combination of cultural and natural heritage sites, including cultural landscapes, which highlight the close, often intangible interactions between humans and their environment, reflect an important evolution in thinking about heritage. Although rooted in a pragmatic reliance on national systems for identification, nomination, and protection, the World Heritage Convention promotes the need for international cooperation for heritage protection in the common interest of humanity.

Underwater Cultural Heritage

In 1985, a team of explorers led by Robert Ballard located the wreck of the RMS *Titanic* in international waters at a depth of more than 4,000 m. The discovery signaled the opening of the deep seas for shipwreck exploration, not only for scientific purposes but also for treasure hunting and commercial exploitation. Indeed, the *Titanic* itself soon became the focus of a controversial, multi-year commercial project. Concerned that underwater cultural heritage in international waters might become the target for the same types of destructive exploitation that had plagued shipwrecks and other submerged sites in the territorial seas in recent decades, in 1994, the private International Law Association developed a draft convention to protect underwater cultural heritage. In 1997, UNESCO decided to promote an underwater convention and, after 4 years of discussions among governmental experts, produced the *Convention on the Protection of the Underwater Cultural Heritage*, which was adopted in 2001 (O'Keefe 2002; Forrest 2010: 287–361).

The Underwater Convention creates a complex and cumbersome regime for the protection of underwater cultural heritage, focusing on the maritime zones beyond the territorial seas, especially the Exclusive Economic Zone (EEZ)/Continental Shelf (up to 200 nautical miles wide) and the "Area," that is, the seabed below the high seas beyond the continental shelf and coastal state jurisdiction. It seeks to balance multiple, often competing interests, including national security, sovereign interests in submerged state vessels and aircraft, and the interests of groups involved in salvage, treasure hunting, sport diving, archaeology, and recreation. The convention takes as its starting point the 1982 *United Nations Law of the Sea Convention* (UNCLOS), which dealt with submerged cultural resources only in a marginal and confusing manner. UNCLOS did, however, establish the principle that states have a duty to protect submerged cultural heritage, should cooperate in that effort, and that "all objects of an archaeological and historical nature found in the Area should be preserved or disposed of for the benefit of mankind as a whole. . ." (Article 149).

Instead of attempting to determine issues of ownership of underwater cultural heritage in international waters, the 2001 convention focuses on rules to ensure that underwater sites will be protected and that activities directed towards them will be conducted according to preservationist principles and archaeologically sound practice. Key principles include the goals of protection and preservation for the benefit of humanity international cooperation, in situ preservation as a first option, long-term preservation and curation of recovered heritage, prohibition of commercial exploitation, respect for human remains, and reasonable public access. The convention requires that activities directed towards underwater cultural heritage be consistent with a set of rules for archaeological best practice based largely on, but not identical to, a document developed by the International Council of Monuments and Sites as the Charter on the Protection and Management of Underwater Cultural Heritage.

The main protective regime envisioned by the 2001 Underwater Convention involves a series of rules for reporting submerged heritage and enforcement actions in two zones – the EEZ/Continental Shelf and the Area. In both

zones, States Parties that discover or intend to undertake activities involving underwater cultural heritage must report their findings or intentions. In the EEZ/Continental Shelf, the coastal state has certain rights to protect submerged sites as well as to authorize or prohibit actions directed towards underwater cultural heritage. In the Area, these responsibilities are more diffuse, and all interested States Parties may become involved in protective efforts in cooperation with a "Coordinating State." To protect sites from unauthorized activities, removals, and looting, States Parties are given a number of enforcement tools to prevent and deter illicit activities. They may prevent the entry into their territory, dealing in, and possession of underwater cultural heritage that has been illicitly recovered and/or illicitly exported. They may seize and dispose of underwater cultural heritage that was recovered in violation of the convention. States Parties may also prohibit the use of their territory, including ports and facilities, in support of any activities directed at underwater cultural heritage in contravention of the convention, and they may take measures to ensure that their nationals and flag vessels do not engage in activities in contravention of the convention.

These tools, in addition to provisions aimed at promoting international cooperation, information sharing, public awareness, and training in underwater archaeology, make the 2001 Underwater Convention a potentially significant tool for protecting underwater sites and diminishing the plague of looting and other unauthorized destruction. To be effective, however, the convention needs broader participation (there are currently 40 States Parties) from countries with active salvage economies and treasure-hunting enterprises, such as the United States and United Kingdom.

Intangible Cultural Heritage

UNESCO's 2003 *Convention for the Safeguarding of Intangible Cultural Heritage* marks a significant departure for international cultural heritage law and policy (Forrest 2010: 362–387). All earlier conventions dealt with tangible cultural heritage, whether movable or immovable, above ground or below the sea. The 2003 convention deals with a difficult and challenging concept of intangible cultural heritage, which it defines in such a way that it also includes some elements of material culture: "The 'intangible cultural heritage' means the practices, representations, expressions, knowledge, skills – as well as the instruments, objects, artefacts and cultural spaces associated therewith-that communities, groups and, in some cases, individuals recognize as part of their cultural heritage" (Article 2(1)). The purpose of the convention is to safeguard the intangible cultural heritage; to ensure respect for it; to increase awareness of, and appreciate for, intangible cultural heritage at local, national, and international levels; and to provide for international cooperation and assistance.

The Intangible Cultural Heritage Convention is rooted in a growing awareness of the need to protect and promote cultural diversity and traditional practices and ways of knowing among the world's peoples, including individuals, indigenous peoples, and ethnic, religious, and linguistic minorities. Its structure follows the approach taken in the 1972 World Heritage Convention, namely, to encourage sovereign states to identify and nominate intangible cultural heritage present in its territories. As in the 1972 convention, an intergovernmental committee is established to register nominated examples of intangible cultural heritage in an inventory, called the Representative List of the Intangible Cultural Heritage of Humanity. Corresponding to the 1972 convention's List of World Heritage in Danger is the new convention's List of Intangible Cultural Heritage in Need of Urgent Safeguarding. The intergovernmental committee also handles requests for international cooperation and assistance and for funding.

Since 2008, a total of 213 "elements" of intangible cultural heritage have been inscribed on the Representative List. Examples include acupuncture of traditional Chinese medicine, the chant of the Sybil on Mallorca (Spain), the Kirkpinar Oil-Wrestling festival in Turkey, the gastronomic meal of the French, and traditional Azerbaijani carpet weaving in Azerbaijan. A total of 16 elements of listed intangible heritage are currently on the list in need of urgent safeguarding, including wooden movable-type printing in China; the Mongol epic tradition known as the Mongol

Tuuli; and the Sanke mon, a collective fishing rite among the Sanke people of Mali.

Conclusion

The international law of cultural heritage continues to evolve as it faces challenges of consistency, definition, and consensus. Threats against both tangible and intangible cultural heritage continue to diminish the common heritage of humanity. The six cultural heritage conventions described in this entry were developed over more than 50 years. They reflect a multitude of interests, concerns, and approaches that continue to change and evolve. Much of the criticism that has been leveled against the cultural heritage conventions has focused, with good reason, on their imperfect effectiveness. Armed conflict still destroys cultural sites; looting still rips ancient artifacts from their archaeological contexts; and the inexorable forces of development and construction continue to destroy cultural sites and disrupt living traditions and cultural practices. Despite these problems, however, the cultural heritage conventions remain the starting point for any discussion of cultural heritage preservation and policy at the international level. Although their implementation may be imperfect, they express normative standards relating to the value and importance of cultural heritage as the common legacy of humankind. Despite the many differences among the individual conventions, they all promote three consistent themes – that cultural heritage is important for peoples, nations, and the world; that cultural heritage is deserving of safeguarding and protection; and that international cooperation and efforts should be devoted to that purpose.

International Council for Archaeozoology (ICAZ)

László Bartosiewicz
Osteoarchaeological Research Laboratory, Stockholm University, Stockholm, Sweden

Introduction

The International Council for Archaeozoology (ICAZ, http://www.alexandriaarchive.org/icaz/) is devoted to the study of human-animal relationships

over time using archaeological evidence. Archaeozoologists have contributed to studies of human impact on the environment on a national level. However, international comparisons between sites are indispensable in such projects. Research questions and methods need to be carefully coordinated. ICAZ is dedicated to promoting communication between archaeozoologists worldwide coordinating policies of recovery and analysis. International cooperation has been a key to understanding, e.g., past impacts of climate change or cultural diversity in ancient diets.

History, Growth, and Impact

Archaeozoology began in mid-nineteenth-century Europe. In 1851 Japetus Steenstrup and his team established the artificial nature of prehistoric shell middens in Denmark. Help by the paleontologist Ludwig Rütimeyer (Bartosiewicz 2001) was enlisted in quest of Celtic Helvetii at Swiss lacustrian settlements in the 1860s.

For a century archaeozoologists operated in relative isolation. The "Great Generation" emerging in the 1950s – predominantly in Central Europe – was natural scientists whose efforts were rarely integrated with archaeological inquiry traditionally concerned with historical interpretations. During the 1960s new New Archaeology in the English-speaking world and concern with environmental issues stimulated archaeozoological research within archaeology.

The first major meeting of archaeozoologists took place as Session IV, of the Third International Congress of Agricultural Museums in Budapest (1971). Seventy-five attended, most from European countries (Matolcsi 1973). They represented both sides of the Iron Curtain, a remarkable phenomenon after the failed 1968 "Prague Spring" in Czechoslovakia. However, thanks to political tolerance at the time, Hungary became equally accessible to archaeozoologists from Eastern Europe and those from the West. Crucially, many attending archaeozoologists already had personal contacts before. Some were separated by the Berlin Wall only after 1961. Sándor Bökönyi, a Hungarian organizer, had already built British and US contacts working in Yugoslavia and Iraq (Bartosiewicz and Choyke 2002). The informality of personal conduct and keen awareness of the need to crosscut political boundaries have become traditional strengths of ICAZ. It was decided that International Conferences should be held every 4 years alternating between Eastern and Western Europe. Meetings thus followed in the Netherlands, Poland, and Great Britain. Although the pattern was abandoned in 1986 by holding a meeting in France, political changes in Europe soon made the East-West distinction irrelevant. The 1990 conference in Washington DC was a breakthrough in ICAZ history: it was the first International Conference held in the New World, right after the political transformation of Europe. It served as a forum for scholars in North America and countries from the former Soviet Bloc who had previously been quite isolated.

Along with growth diversity has increased. Regional representation varied in the International Conference proceedings, the best proxy to the scholarly involvement with ICAZ. Figure 1 shows ICAZ activity in print. There is an increase in scholars from outside Europe, mostly North America (Amorosi et al. 1996). On the margins of the graph, welcome contingents from Africa, Asia, Australia/New Zealand, and Latin America began appearing already over a decade ago. Standardized publication data have not been available for recent conferences: they are too costly to be taken on board by a single publisher; output is spread among conference sessions. The high contribution of local participants in Fig. 1 has highlighted an important aspect of conferences: the publicity provided by hosting meetings. This benefit was foreseen by the founders when alternating East-West venues were planned.

Since then ICAZ has grown into a global organization. International Conferences should be held on a different continent every 4 years in an effort to guarantee access. Additional International Conferences held in the Americas included those in Canada (1998), Mexico (2006) and Argentina (2014). The 2018 meeting is planned in Turkey. The 2010 International Conference in Paris was devoted to promoting archaeozoology in Central and Eastern

International Council for Archaeozoology (ICAZ), Fig. 1 Regional representation as reflected in International Conference proceedings. After 1990 Eastern Europe includes former Soviet Bloc countries except for East Germany

Europe. Not all archaeozoologists in large countries such as China, India, or Russia have had full access yet to ICAZ membership. The Paris conference was of special importance in including colleagues from areas outside the usual geographical range of ICAZ membership. It mustered 714 registered participants from 56 of the 61 countries represented in ICAZ, a spectacular increase since 1971 (Budapest, 75 participants, 18 countries).

As a qualitative consequence of growth, subtopics within archaeozoology began attracting attention and working groups specialized in ICAZ. They are loose, autonomous groups. Their meetings are organized every 2–3 years. In 2018 sixteen such groups were registered, some specializing in regions (e.g., SW Asia) and others by taxonomic groups (e.g., fish). In addition to evident diversification, the dynamic development of working groups is also evident as many functions are taken over from the overgrown, multi-session International Conferences.

Transforming ICAZ into a membership-based professional organization was initiated at the 1990 Washington DC meeting. By 2003 a dues-paying membership was created. Most of the income is being redistributed every 4 years to support conference participation for those most in need and other costs of communication. Organizing International Conferences with a global outreach has become a heroic task both financially and in terms of logistics. In addition to geographical affiliation, the age and employment status of potential participants have been consistently considered in funding (Vigne and Lefèvre 2010).

ICAZ is committed to its founding goal of fostering communication within the diverse archaeozoological community. Although Europe became politically united, other tensions create what is politely referred to as "visa issues." Access to conference venues is not equally guaranteed to everyone, and the wisdom of ICAZ founders would be needed to outwit political forces beyond the power of an academic organization. Solidarity and personal trust among members remain the fundamental assets in best handling such inevitable situations.

International Council of Museums (ICOM)

Julien Anfruns
ICOM, Maison de l'UNESCO, Paris, France

Basic Information

The International Council of Museums (ICOM; icom.museum), since its inception in 1946, is the world organization for museums and museum professionals, committing to the promotion and protection of natural and cultural heritage, the present and future, tangible and intangible. With over 30,000 members in 137 countries, ICOM is a network of museum professionals acting in a wide range of museum- and heritage-related disciplines (Fig. 1).

International Council of Museums (ICOM), Fig. 1 ICOM logo

Major Impact

Maintaining formal relations with UNESCO and a consultative status within the United Nations Economic and Social Council, ICOM takes part in the development and the implementation of international conventions that play a crucial role in the protection and the promotion of cultural heritage: the 1954 Hague Convention *for the Protection of Cultural Property in the Event of Armed Conflict* and its two Protocols, the 1970 Convention *on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property*, the 1972 Convention *Concerning the Protection of the World Cultural and Natural Heritage*, and the 2003 Convention *for the Safeguarding of Intangible Cultural Heritage*. ICOM has also initiated close partnerships with the UNESCO Memory of the World Program.

ICOM partners other organizations such as the World Intellectual Property Organization (WIPO), INTERPOL, and the World Customs Organization, in order to carry out its international public service missions. Together, ICOM and its partners strive particularly to make awareness-raising efforts highlighting the importance of protecting the cultural heritage of civilizations against illicit traffic, assist museums through alternative dispute

resolutions in the process of complex negotiations, and provide support and risk prevention tools for cultural institutions facing conflict situations or natural disasters.

In the field of relief response for heritage, ICOM is a founding member of the International Committee of Blue Shield (ICBS). This equivalent of the Red Cross for Heritage relates to the UNESCO Hague Convention (1954) to protect cultural goods during armed conflicts. In this regard, the International Committee of the Blue Shield (ICBS) works to protect world cultural heritage threatened by natural and man-made disasters.

ICOM's commitment to culture and knowledge promotion is reinforced by its 31 international committees dedicated to a wide range of museum specialities, who conduct advanced research in their respective fields for the benefit of the museum community. ICOM has therefore the ability to mobilize experts in cultural heritage worldwide responding to the challenges museums face around the globe.

A leading force in ethical matters, ICOM adopted its *ICOM Code of Ethics for Museums* in 1986, a reference tool that sets standards of excellence to which all members of the organization must adhere. The *ICOM Code of Ethics for Museums*, translated into 36 languages and revised in 2006, establishes values and principles shared by ICOM and the international museum community. These standards of self-regulation by museums include basic principles for museum governance, the acquisition and disposal of collections, and rules for professional conduct.

ICOM provides for its members various resources to foster their professional network and expertise: the UNESCO-ICOM Museum Information Centre, the *ICOM News* magazine, a monthly e-newsletter with information on events within the ICOM network, and ICOMMUNITY, an online collaborative platform for ICOM members to exchange and share information more easily.

Finally, ICOM organizes a wide range of events for all museum lovers and professionals. Since 1977, each year ICOM has organized the International Museum Day, an event held worldwide around the 18th of May to promote greater diversity and intercultural dialogue amongst the international museum community. Furthermore, academic events take place internationally as ICOM's committees hold annual conferences and symposiums revolving around themes relating to their expertise and specialities, with the gathering of high-ranking specialists. Finally, the ICOM General Conference is held triennially as an opportunity for the international museum community to come together and engage in professional discussion on the issues facing museum professionals today. Different countries host this conference: Seoul in 2004, Vienna in 2007, Shanghai in 2010, and Rio de Janeiro in 2013.

International Council of Museums (ICOM): Code of Ethics

Abdoulaye Camara
IFAN Ch. A. Diop, Université de Dakar, Dakar, Senegal

Introduction

The International Council of Museums (ICOM) (http://icom.museum/), created in Paris in 1946, is an international organization of museums and museum professionals whose mission is the conservation and transmission of natural and cultural heritage, present and future, material and immaterial. This mission demands the acceptance of the Ethical Code, for the museums and the professional members of the ICOM, which was adopted during the organization's 15th General Assembly in Buenos Aires, Argentina on November 4th, 1986. This code, which was last revised in 2006, establishes the common values and principles of the ICOM and of the global museum community in English, French, and Spanish.

The Code of Ethics of the ICOM is presented as a series of principles and rules which govern professional practices for the museums and their staff and thus established professional standards applicable to all members. These norms play a quasi-legal role in countries where legislation is lacking or unclear regarding professional practices to adopt. They can also serve as a basis for responding to local requirements or to other queries of museum staff.

The Code of Ethics of the ICOM (http://icom.museum/professional-standards/codeof-ethics/) consists of eight chapters which outline each principle and related articles.

Key Issues/Current Debates/Future Directions/Examples

1. *Museums preserve, interpret, and promote the natural and cultural inheritance of humanity*

Cultural property of which museums interpret and are responsible for, are not only significant elements for the definition of cultural identity, both nationally and internationally, but they also often provide essential evidence to many disciplines in the humanities or natural sciences, thereby representing an important contribution to knowledge.

To achieve this mission, the regulatory authorities, in their management, must have authorization documents clearly stating the legal status of the museum, its mission, duty, and non-profit character (1.1 to 1.2); premises that are secured against most risks, while providing an appropriate environment that is accessible to all; and housing the collections, staff, and visitors in compliance with all relevant health, safety, and security provisions (1.3 to 1.8).

Still under the regulatory authority, the funds coming from public or private sources or income-generating activities must comply with the norms of the museum and the public and be used for the realization and development of the institution's activities (1.9 to 1.10); and in compliance with museum policies and legal and regulatory procedures, the skills of all the staff and volunteers are used in the context of an ethical conduct of the highest rigor and a professional approach offering possibilities for continual training in order to maintain efficiency (1.11 to 1.18).

2. *Museums that maintain collections hold them in trust for the benefit of society and its development*

The museum is defined as an institution that acquires, conserves, researches, communicates,

and exhibits the tangible and intangible heritage of humanity and its environment.

Within the framework of acquisition, disposal, protection, and utilization of collections, the museum must adopt a charter under the direction of the regulatory body, prove their diligence in establishing the complete history of the object from its discovery or its creation, and ensure that the object possesses a valid title; that it was not illegally obtained in, or exported from, its country of origin or any intermediate country in which it might have been legally owned (2.1 à 2.3); and that its acquisition did not involve the unauthorized, unscientific, or intentional destruction or damage of monuments, archaeological or geological sites, or species and natural habitats (2.4).

The acquisition should be based on an ethic where the choice of values was not imposed but was freely chosen by the responsible authorities. Moreover, concerning the collection, research, and exhibition of collections composed of human remains or sacred objects, it is recommended to treat this sensitive material with respect and in accordance with the interests and beliefs of members of the community, ethnic, or religious groups (2.5, 3.7, and 4.3).

Similar provisions are realized for biological and geological specimens (2.6) and living organisms (2.7) whose acquisition and conservation must respect the relevant legislation associated with the protection of species, nature, and the environment. For living animals, the museum assumes total responsibility for their health and well-being and should prepare and implement a safety code approved by an expert in the veterinary field (2.25).

Nevertheless, it is possible that the institution acquire objects in exceptional circumstances without an attested provenance and outside the museum's stated policy. For these exceptional acquisitions, the regulatory authority can take into consideration the advice of professionals, without national or international bias, the specific interests of the object for its preservation, and the legality of the title of ownership (2.9 and 3.4). It can also authorize the museum to act as a repository for objects illegally collected from the territory in which its lawful responsibility has been established (2.11).

The removal, just like the acquisition, of an object is subject to legal conditions and obligations. The museum can definitively dispose of an object or specimen from its register and collection by donation, transfer, exchange, sale, repatriation, or destruction of infested and deteriorated objects. It is up to each institution under the authority of its governing body, and in conjunction with the director of the museum and curator of the collection, to decide the procedure to follow in similar cases, to ensure that the money or benefits obtained are employed for the benefit of the collection, and to prevent members of the museum staff as well as their families or close associates from purchasing the objects from the collection for which they are responsible (2.12 à 2.17), or making personal use of objects from the collection of the museum (2.26).

To ensure its service, the collections are entrusted to qualified personnel. The documentation should meet accepted professional standards: full identification and description of each item, its associations, origin, condition, treatment, and present location in the museum. The collected data, to be used for securing, preventative conservation, or restoration, should be kept in a secure environment and managed by documentation retrieval systems enabling access to the information by the museum personnel and other legitimate users who are likely to consult them in the context of the museum's development (2.18 à 2.20).

A strategy should aim at protecting collections from disasters (armed conflicts and other human-made or natural catastrophes), guaranteeing the confidentiality of information, and to prevent any risks relating to the conservation of objects in an inappropriate environment during storage, display, or transit. This strategy must be developed by the museum responsible for monitoring the condition of object to determine when an object may require professional restoration (2.21 to 2.24).

3. *Museums hold primary evidence for establishing and furthering knowledge*

As institutions of general interest, museums possess collections that are primary evidence dedicated to knowledge. In this regard, the collection and all associated information should be made accessible and document the complete history of the object since its discovery. Field collection and research undertaken by museum staff should be carried out in accordance with the scientific norms, national and international legislative obligations, as well as with respect and consideration for the views of local communities within the missions and goals of the museum (3.2 to 3.5). The nature of collections means that members of the museum profession can share their knowledge and experience with researchers and students in relevant fields. The investigations carried out in this context should promote the use of information relating to collections and prevent all activities that could lead to the loss of scientific data which would be useful to develop within the framework of a necessary cooperation with other institutions sharing the same interests and collecting practices (3.6 to 3.10).

4. *Museums provide opportunities for the appreciation, understanding, and promotion of the natural and cultural heritage*

The proliferation of exhibitions mainly intended for the public's enjoyment and to reach a wider audience should take into account the ethical aspects relating to the mission, beliefs, and discretions accorded to some objects. The museum should be aware of the demands for the removal of objects coinciding with the sensitivities of a community, ethnic, or religious group from whom the object originated, or simply objects of questionable origin or lacking provenance information, which can be perceived as an encouragement for the illicit trafficking of cultural goods (4.1 to 4.5). For its educative mission, the museum should only publish accurate information and give consideration to the academic disciplines, societies, or beliefs presented (4.6). Finally, the presentation of collections inviting the public to participate in knowledge and culture must respect the integrity of the original and signal replicas, reproductions, or copies as facsimiles (4.7).

5. *Museums hold resources that provide opportunities for other public services and benefits*

The museum has the ability, through its identification service or that of another museum, to carry out this activity without it being considered as work benefiting them. If the identification and authentication reveal that objects are suspected of having been illegally acquired, this should not be made public until the appropriate authorities have been notified (5.1).

The estimation of monetary value, when it is undertaken by a museum in order to insure its collections, should only be given in response to an official request by other museum authorities or other appropriate authorities. However, when the museum itself may be the beneficiary, appraisal of an object or specimen must be undertaken independently (5.2).

6. *Museums work in close collaboration with the communities from which their collections originate as well as those they serve*

The ICOM encourages museums to promote the sharing of knowledge, documents, and collection, to develop partnerships, and to engage in dialogue with museums and other cultural organizations from the countries that have lost a large part of their heritage with a view to return cultural property (6.1 and 6.2).

Claims for restitution, which are regularly made for cultural property, concern all specimens or objects that appear to have been exported or otherwise transferred in violation of the principles of international and national conventions, or bought or acquired from an occupied territory disregarding the laws governing the importation, exportation, and transfer of cultural or natural materials.

Museums must conduct activities in close cooperation with the communities from which their collections originate as well as the communities they serve. The respect for concerned communities should prevail over all other activities

(collecting, searching for funds) carried out by the museum aiming to use its collections (6.3 to 6.8).

7. *Museums operate in a legal manner*

Museums should define their role and act with regard to a concerted ethical conduct in accordance with local and national laws in their location (7.1); they must direct their policy according to international legislation which serves as the standard for the interpretation of the ICOM's Code of Conduct, namely, the principle conventions listed in article 7.2:

- UNESCO Convention for the Protection of Cultural Property in the Event of Armed Conflict (The Hague Convention, First Protocol, 1954, and Second Protocol, 1999)
- UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (1970)
- Convention on International Trade in Endangered Species of Wild Fauna and Flora (Washington, 1973)
- UN Convention on Biological Diversity (1992)
- UNIDROIT Convention on Stolen and Illegally Exported Cultural Objects (1995)
- UNESCO Convention on the protection of the Underwater Cultural Heritage (2001)
- UNESCO Convention for the Safeguarding of the Intangible Cultural Heritage (2003)

8. *Museums operate in a professional manner*

Professional conduct compliant with ethical standards should dictate that all members of the museum institution have a good understanding of relevant legislation to protect them from deviant behavior (8.1), to distance them from practices that are contrary to professional ethics (8.2), and to encourage them to conform to the terms of the Code of Ethics of the ICOM and to know all the other codes or policies concerning museum work (8.3). Members of the museum profession are scientifically and intellectually responsible for all activities that may lead to the loss of information. They also have other obligations, such as never participating to illicit traffic (8.5), or protecting all confidential information related to their activity or possessed by the institution concerning the collection or the security of locales (8.6 to 8.7). The exception to the obligation for confidentiality involves goods which are illegally acquired and which are the object of police or legal investigations (8.8). Private or professional activities, as well as work relations conducted internally and externally to the museum, cannot be separated from those of their institution and should enable professionals to carry out their services efficiently and to a high standard in consultation with colleagues within or outside the museum (8.9 to 8.11).

Members of the museum profession should take into account the conflicts of interest that may arise from the benefits that could be offered to them because of their function (8.12), the specialist activities undertaken by them outside the institution (8.13), their direct or indirect participation in dealing (buying or selling for profit) natural or cultural heritage (8.14), maintaining relationships with dealers leading to the acceptance of gifts and donations in whatever form (8.15), and collecting objects privately that could compete with their institution (8.16).

Finally, ICOM requests all members to not use the same acronym or logo of the organization to promote or endorse any for-profit operation or product (8.17) and encourages them, in all other conflicts of interest between a person and the museum, to keep the interests of the museum prevailing (8.18).

Conclusion

The code of ethics for museums does not have a legal value in a strict sense but it states the precepts of conduct that set a high moral value to which each member of the ICOM is committed. Within the organization, the Ethics Committee is responsible for ensuring compliance with the code, to consider all matters pertaining to professional ethics to museums, to ensure its execution, and to propose to the Executive Board any

changes or supplement to the code (ICOM n.d.). The committee is called upon by the Executive Council as well as by various national and international organizations to study the codes of ethics developed by other bodies of the organization (Internet Museum n.d.).

International Council on Monuments and Sites (ICOMOS) (Ethics)

Sarah Madole
New York University, New York, NY, USA

Basic Information

Committed to neutral and sustainable monitoring of archaeological sites, especially during periods of social crisis or instability, the International Council on Monuments and Sites (ICOMOS) is a nongovernmental, professional organization dedicated to the conservation and protection of historic monuments, sites, and places throughout the world. Its website is at www.icomos.org.

History

COMOS was founded in Warsaw in 1965 as part of the 13 resolutions adopted in 1964 by the Second Congress of Architects and Specialists of Historic Buildings, which aimed in part to form an ethically responsible and globally recognized principle for the treatment of historic monuments. The first resolution, the Venice Charter, created the International Charter for the Conservation and Restoration of Monuments and Sites. ICOMOS was established in order to carry out this resolution. The Venice Charter traced its doctrinal roots to the 1931 Athens Charter on historic buildings. The pioneering Athens Charter put forth a fundamental definition of international cultural heritage and acknowledged the importance of creating globally accepted policies that reflect the ethical treatment of internationally recognized cultural heritage sites.

Major Impact

Advisory Body to the World Heritage Committee

In 1972, UNESCO named ICOMOS one of three official advisory bodies to counsel the World Heritage Committee on candidates for inclusion in the World Heritage List. ICOMOS considers individual monuments, sites, and places for nomination. The fundamental quality for consideration, as outlined by the World Heritage Convention, is "outstanding universal value" (OUV) (Jokilehto 2008). ICOMOS evaluates three additional primary criteria: authenticity, management, and conservation.

The necessarily broad definition of cultural heritage embodies a dynamic range of approaches to the conservation and protection of monuments, sites, and places. Various charters and memoranda have continued to reshape the mission of ICOMOS in identifying potential candidates for the WHL. One of the most important documents in the development of the notion of cultural heritage is the Florence Charter, an addendum to the

Venice Charter. This 1982 doctrine was created in order to include living entities as candidates for World Heritage Sites, in this instance, the gardens in the historic center of Florence. A second document should also be mentioned. As part of the 2005 World Heritage Convention, the Vienna Memorandum clarified the potential candidacy of entire cities (or Historic Urban Landscapes) for inclusion in the WHL (Araoz 2008). Such reevaluations of conceptual criteria underscore the vigorous, collaborative objectives of ICOMOS in defining and protecting world heritage.

International Committee of the Blue Shield, Risk Management

ICOMOS maintains at least one principal function in addition to advising the WHC. ICOMOS is one of five nongovernmental organizations that comprise the International Committee of the Blue Shield, founded in 1996. The Blue Shield emblem, the cultural counterpart of the Red Cross, was first issued as a result of the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict. This particular function of the Blue Shield and, by extension, ICOMOS calls for the protection of historic monuments, sites, and places in areas of crisis. The committees advising the Blue Shield aim to stop the destruction of internationally recognized cultural heritage during periods of violent conflict. In 2011, Blue Shield emblems were issued for armed conflicts in Egypt, Libya, and Syria.

A second Blue Shield statement on Syria was issued in 2012. An extension of ICOMOS' role advising the International Committee of the Blue Shield is its commitment to risk management in crisis situations. From January 7 to 8, 2013, an ICOMOS International Scientific Committee, the International Scientific Committee on Risk Preparedness (ICORP), led an e-learning course for professionals in cultural heritage currently living in Syria. This reflected a collaborative effort with ICOMOS-ICORP, UNESCO, ICCROM (International Centre for the Study of the Preservation and Restoration of Cultural Property), and the DGAM (Directorate-General of Antiquities and Museums of Syria). This particular endeavor sought to improve the multi-level of preparedness of Syrian cultural heritage experts in various aspects of risk management and emergency response, in moments of conflict, and in the aftermath.

Committees, Membership, and General Assemblies

ICOMOS is comprised of two main branches, the Executive Committee and Secretariat, which are based at the international headquarters in Paris and individual or institutional members of National Committees. A third component, the International Scientific Committees, was comprised of 26 committees in January 2013. At that time, membership count was listed as approximately 12,100 members worldwide. National Committees are active in 110 countries. Each National Committee, regardless of the number of members, is allocated a maximum quota of 18 votes at general assemblies. Each National Committee operates within its own rules of procedure, although these must adhere to the basic premises of ICOMOS. Eligibility for membership is contingent upon the applicant's professional involvement in a field concerning cultural heritage. This definition includes, inter alia, professionals working in various aspects of conservation (scientific, technical, and administrative), and it may also include those working in disciplines such as archaeology, ethnology, and town planning. Membership is contingent upon adhering to an Ethical Commitment Statement currently comprised of 15 articles, each of which requires the active personal and professional involvement of members in various aspects of cultural heritage preservation. This statement is intermittently reviewed by members in order to ensure that it reflects contemporary ethical and methodological concerns in cultural heritage. A significant element of ICOMOS' general mission is for its doctrine to evolve as new situations arise that require nonpartisan council. Therefore, membership is contingent upon individual commitment to promoting and engaging with each of the 15 articles

in current situations. Article 4, for example, requires that ICOMOS members stay apprised of "contemporary conservation philosophy, practice and techniques" and whenever applicable that members share and exchange such information (*Ethical Commitment Statement for ICOMOS Members* 2002).

ICOMOS operates via international general assemblies. By the end of 2011, there will have been 17 general assemblies, during which representatives from Executive and National Committees meet to vote on and evaluate doctrinal issues. Records of the general assemblies (starting in 1965) as well as ICOMOS executive and advisory committee meetings (starting in 2006) are published on the ICOMOS website (ICOMOS n.d.).

International Day for Monuments and Sites

In 1983, UNESCO approved the ICOMOS proposal to make April 18th the International Day for Monuments and Sites, in order to annually promote different aspects of cultural heritage. The theme successfully nominated by ICOMOS in 2011 was the "Cultural Heritage of Water," which reflects the expanding awareness and definition of cultural heritage (McIntyre-Tamwoy et al. 2011). Previous themes include Religious Heritage and Sacred Spaces (2008) and twentieth Century Heritage (2002).

International Council on Monuments and Sites (ICOMOS) (Museums)

Grellan D. Rourke
National Monuments, Office of Public Works, Dublin, Ireland

Basic Information

The Second International Congress of Architects and Specialists of Historic Buildings, meeting in Venice in 1964, adopted 13 resolutions, the first one being the Venice Charter and the second, put

forward by UNESCO, provided for the creation of the International Council on Monuments and Sites (ICOMOS). Its statutes set out the aims and activities of the organization, the composition of membership, its administrative structure, and its legal status. It is one of the three formal advisory bodies to the UNESCO World Heritage Committee and is a representative on the International Committee of the Blue Shield, the cultural equivalent of the Red Cross. ICOMOS is an association of professional experts that currently brings together over 12,000 members throughout the world, organized through National Committees. It is interdisciplinary and works for the conservation and protection of cultural heritage places. It is the only global nongovernment organization of this kind, which is dedicated to promoting the application of theory, methodology, and scientific techniques to the conservation of the architectural and archaeological heritage.

The General Assembly, which meets every 3 years, is the sovereign body of ICOMOS comprising all its members worldwide. It elects the President, the Vice-Presidents, the Secretary General, and the Treasurer General, who together make up the Bureau. It also elects the 12 members of the Executive Committee. The General Assembly determines the program and the budgetary orientations for the triennium to come and sees that the objectives of ICOMOS have been met. Parallel to the elections and the statutory proceedings, a major international symposium is held on a different theme each time.

The Advisory Committee comprises the Chairs of the National Committees and International Scientific Committees. It meets once a year and its function is to advise the Executive Committee by bringing forth suggestions and recommendations on program priorities and orientations. The Executive Committee is the managing body of ICOMOS. It has 12 members, in addition to the members of the Bureau and 5 co-opted members. Demonstrated professional qualities are a requirement for these members, who represent every major region of the globe. The Executive Committee prepares the program and budget and oversees their implementation; between sessions it is the Bureau that ensures the program is implemented. The International Secretariat, located in the headquarters in Paris, is managed by an operational team led by a director and coordinates the implementation of the program. It has three divisions: Administration, World Heritage, and Documentation (UNESCO-ICOMOS Documentation Centre).

Major Impact

ICOMOS has established 28 International Scientific Committees (ISCs) on various cultural heritage themes. Members consist of international renowned expert specialists in each subject and are designated by their own National Committee. The ISCs are ICOMOS technical bodies. They undertake research; develop conservation theory, guidelines, and charters and foster training for better heritage conservation; promote international exchange of scientific information; and carry out projects. They elaborate their own programs and publish an annual report subject to the approval of the Executive Committee. ICOMOS has adopted a number of charters, resolutions, declarations, and other technical studies all of which are available on the website: http://www.icomos.org

International Council on Monuments and Sites (ICOMOS): Scientific Committees and Relationship to UNESCO

Helaine Silverman
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Brief Definition of the Topic

ICOMOS is the International Council on Monuments and Sites. It is an international non-governmental organization of professionals concerned with the conservation of historic/archaeological monuments and sites around the world. Quoting from its website (http://www.icomos.org/en/about-icomos/mission-and-vision/mission-and-vision):

> ICOMOS works for the conservation and protection of cultural heritage places. It is the only global non-government organisation of this kind, which is dedicated to promoting the application of theory, methodology, and scientific techniques to the conservation of the architectural and archaeological heritage. Its work is based on the principles enshrined in the 1964 International Charter on the Conservation and Restoration of Monuments and Sites (the Venice Charter).
>
> ICOMOS is a network of experts that benefits from the interdisciplinary exchange of its members, among which are architects, historians, archaeologists, art historians, geographers, anthropologists, engineers and town planners.
>
> The members of ICOMOS contribute to improving the preservation of heritage, the standards and the techniques for each type of cultural heritage property: buildings, historic cities, cultural landscapes and archaeological sites.

ICOMOS refers to "cultural internationalism" in its discussion of its history, in other words, an international concern with the promotion and protection of the tangible cultural heritage. An early impetus toward achieving ICOMOS' aims began in the post-World War I climate that saw the creation of the League of Nations and that climaxed in the immediate post-World War II years following the devastation not just to millions of people but also to the built environment of Europe. The Athens Charter of 1933 had addressed the restoration of historic buildings. The United Nations was created in 1945. UNESCO was created in 1948. The First Congress of Architects and Specialists of Historic Buildings was held in Paris in 1957 and advocated for the protection of historic buildings and membership in the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM). The Second Congress of Architects and Specialists of Historic Buildings in Venice in 1964 produced the important Venice Charter and the birth of ICOMOS.

ICOMOS emphasizes the global coordination role of this organization, directed at establishing an international effort for the preservation and the appreciation of the world heritage of historic monuments. Specifically, the ICOMOS mission is to

- Bring together conservation specialists from all over the world and serve as a forum for professional dialogue and exchange
- Collect, evaluate, and disseminate information on conservation principles, techniques, and policies
- Cooperate with national and international authorities on the establishment of documentation centers specializing in conservation
- Work for the adoption and implementation of international conventions on the conservation and enhancement of architectural heritage
- Participate in the organization of training programs for conservation specialists on a worldwide scale
- Put expertise of highly qualified professionals and specialists at the service of the international community (http://www.icomos.org/index.php/en/about-icomos/mission-and-vision/icomos-mission).

The 1972 UNESCO World Heritage Convention specifically names ICOMOS as one of three formal advisory bodies to UNESCO's World Heritage Committee. (The other two are the World Conservation Union, IUCN, and the International Centre for the Study of the Preservation and Restoration of Cultural Property, ICCROM). ICOMOS's most

important task is to evaluate all nominations of cultural sites that are submitted by the States Parties (the countries that have ratified the World Heritage Convention) to the World Heritage Committee. Among ICOMOS' many scientific committees, ICAHM/International Committee on Archaeological Heritage Management now plays a crucial role in assisting those countries seeking advice on the nominations process, among its other functions. ICAHM is currently working on standards of professional performance (see http://www.icomos.org/icahm/orgchart/ICAHM_Function_OfficesandDuties.pdf) and recently launched a publication series called "Multidisciplinary Perspectives on Archaeological Heritage Management" with Springer Publishing. ICAHM is also concerned to communicate its activities to the general public in the hope of raising awareness about site management, the proper conduct of which furthers ICOMOS' overall goal of site preservation.

The other ICOMOS scientific committees are: Analysis and Restoration of Structures of Architectural Heritage; Documentation of Cultural Heritage; Conservation/Restoration of Heritage Objects in Monuments and Sites; Cultural Itineraries; Cultural Tourism; Earthen Architectural Heritage; Economics of Conservation; Fortifications and Military Heritage; Historic Gardens and Sites; Cultural Landscapes; Historic Towns and Villages; Intangible Cultural Heritage; Interpretation and Presentation; Legal, Administrative and Financial Issues; Pacific Islands; Polar Heritage; Risk Preparedness; Rock Art; Shared Built Heritage; Stained Glass; Stone; Theory and Philosophy of Conservation and Restoration; Training; twentieth Century Heritage; Underwater Cultural Heritage; Vernacular Architecture; Wall Paintings; and Wood. Obviously, not all of these ICOMOS scientific committees are concerned with the archaeological past.

International Cultural Tourism Charter Managing Tourism at Places of Heritage Significance (1999)

Brian Long
Faculty of VCA & MCM, University of Melbourne, Southbank, VIC, Australia

Introduction

Around the world local, regional, and international tourism has grown significantly in importance since the end of World War II. Tourism is now a major employer in rural and urban areas across the world. In many communities, it is now one of the largest sources of economic activity. The numerical growth of the middle class in many emerging economies coupled with the emergence of mass-market air travel means that a greater proportion of the global population is now able to enjoy leisure travel than ever before. Similarly, the spread of mass communication media, such as television and cinema, combined with improved education in most countries has stimulated a desire in many people to visit other places and to experience other cultures.

While the early years of postwar mass tourism often concentrated on outdoor leisure pursuits and relaxation, the last 30 years have witnessed a fragmentation and diversification of the tourism industry. Consumer, adventure, family, sport, cultural and eco-tourism are now recognized sectors of the industry and they, too, contain further

subsectors. If we understand culture in the way that anthropologists do – as the way of life and shared values of a particular community – then all tourism is cultural. Even a beachside holiday takes place in the context of a certain way of life and specific shared values. So the various forms of tourism rarely exclude a mixture of objectives on the part of travelers and visitors. Beach holiday makers may include in their holiday plans a visit to a historic site or museum. People who are primarily interested in experiencing the arts, heritage, or historically significant sites may also want to spend time in a resort or on the ski fields.

Tourism operators, too, usually cater to varying needs. There are many ways to experience any tourist site. When we talk, then, of cultural tourism, it is a category that differs from other types of tourism in its emphasis and prioritization of the cultural aspects of the visitor experience. Almost all travelers are cultural tourists in some sense or at some time.

Cultural tourism can, however, be an area of contention because many sites, objects, and practices of cultural significance were never intended to host large numbers of visitors. When poorly managed, tourism can cause irreparable damage to cultural places or artifacts. The desire to attract visitors must be balanced by the need to preserve artifacts, traditions, or sites for others. It is also important that visitors respect and seek to understand the cultures of other people. Conflicts between ideas of individual and group ownership of cultural artifacts, sites, and traditions also need to be taken into consideration. While cultural meaning and significance is created by groups of people, individual items or places may rightfully belong to individuals whose rights and interest may conflict with those of the wider community.

Cultural tourism is a growing sector, and demand for tourist experiences with a cultural focus is expected to continue growing (OECD 2009). This growth is in part a reflection of today's demand for cultural authenticity. Visitors to culturally significant sites want firsthand experience of significant artifacts and places (Schouten 2007). This desire, however, also creates challenges for custodians and managers of cultural and environmental heritage. Just as the sheer number of visitors to heritage and culturally significant sites may threaten some of them, so, too, the demand to experience "the real thing" poses challenges for their preservation, especially when the effects of age-related deterioration, exposure to environmental damage, and changing cultural understandings are taken into account. Once again, a careful balancing of the demands of visitors and of preservation is required (ICOMOS 1994). The Charter has at its heart the objective of balancing these different interests.

Definition

Cultural tourism is a term that refers to tourism that has as its primary focus the experience of artistic, historical, or ceremonial aspects of places, artifacts, or practices.

The International Cultural Tourism Charter Managing Tourism at Places of Heritage Significance (1999) was adopted by the International Council on Monuments and Sites (ICOMOS) at its twelfth General Assembly in Mexico in October 1999.

ICOMOS was called into being in 1964 in response to a proposal from the United Nations Educational, Scientific and Cultural Organization (UNESCO). It is an international, non-government, membership-based organization most of whose members are professionals in the heritage, architecture, archaeology, and historical sectors. ICOMOS advises UNESCO and national governments on matters of world, national, and local heritage, and it has adopted a range of charters, resolutions, and declarations concerning aspects of cultural and environmental heritage protection and management. It has various scientific committees including one for cultural tourism.

Key Issues/Current Debates/Future Directions/Examples

The International Cultural Tourism Charter (1999) consists of six principles, seven objectives,

and an introductory statement of its ethos. This opening section explains the thinking behind the document and provides examples of cultural and natural heritage. It also makes clear that the Charter takes a universalist position on culture and cultural heritage. This position asserts that cultures share certain universal values and that heritage "belongs to all people." It is, though, a position that reflects Western Enlightenment ideas about the universality of human experience and culture and is one that is not shared by some other intellectual traditions.

The Introduction to the Charter further makes it clear that we live in an increasingly globalized world. Globalization is often seen as a threat to local cultural traditions and in recent years a number of international initiatives have been implemented with the aim of protecting the diversity of cultures around the world (UNESCO 2005). The Charter Ethos argues that "people everywhere" are challenged to preserve cultural diversity and conserve, present, and interpret cultural heritage. The Charter, nevertheless, recognizes that at the practical level these tasks normally fall to local communities. One of the principal aims of the Charter is to provide guidance to the people of these communities.

A further objective is to encourage the tourism industry to "respect and enhance" the culture of host communities. In many respects, cultural tourism brings with it inherent conflict potential, particularly between the interests of visitors and tourism operators on the one hand, and local communities and cultural custodians on the other. The third of the Charter's objectives is to foster dialogue between "conservation interests and the tourism industry." One of the desired results of this dialogue is the development of management plans that sets goals and strategies for the "presentation and interpretation of heritage places and cultural activities," and this is encouraged in the fourth of the objectives.

The first of the principles contained in the Charter notes the importance of cultural tourism for cultural exchange and calls for the conservation of cultural heritage so as to provide visitors and host communities with firsthand experience of cultural sites. The four subsections of Principle 1 deal with the contemporary significance of natural and cultural heritage, the need for the explanation and interpretation of cultural and natural significance, the fostering of the awareness needed to ensure the survival of heritage and the diversity of cultural meanings attributed to some places.

Principle 2 addresses the potential for conflict between the competing demands made on heritage sites. Its first subsection deals with cultural heritage as a source of "cultural diversity and social development." It calls for policy measures in a range of fields to ensure the protection of cultural manifestations. Later subsections deal with questions of authenticity, conflict resolution, the use of local materials and traditions in conservation programs, the development of management plans, and the implementation of evaluation programs to assess the impact of tourism on sites of cultural significance.

In many cases, the concerns of host communities and visitors to places of cultural interest can be in conflict. For a long time visitors to Uluru in Central Australia thought a visit to this iconic site was best capped with a climb up the famous rock. Many people would still like to do so. But climbing on Uluru conflicts with the cultural importance of the site for the local community – as well as causing environmental damage – and, hence, visitors are discouraged from doing so. In other places, host communities require visitors to dress in a manner appropriate to the meaning of a site, to remove their shoes, to refrain from taking photographs, to maintain silence, and so on in efforts to ensure that tourism does not harm the cultural traditions and meanings of a site or to minimize physical damage. Balancing these requirements with the legitimate interests and desires of visitors is one of the key objectives of the Charter, and one that is embodied, in particular, in subsections 2.2 and 2.6.

The authenticity of the visitor's experience is a crucial element for most cultural tourists. Indeed, the search for cultural traditions and practices that are considered more "authentic" than their own is a key element of cultural tourism for many people, particularly in Western countries. But when considered more closely, authenticity becomes a

contentious concept. The materials used in many historically important buildings are prone to natural deterioration and may need to be replaced. The actual wood we see when we visit a centuries-old Asian temple today may actually be quite recent. Similarly, in many European cities, numerous historic buildings were reconstructed in the aftermath of World War II and while they may appear much older, they are not strictly "authentic" or particularly old. In recent years, this feature of cultural heritage conservation has taken on new dimensions in Berlin where there has been a lively debate about reconstructing the Baroque palace (Stadtschloss) after it was damaged during the war and its ruins removed in 1950. Few people would argue that the resulting urban wasteland should remain unused. But the idea of rebuilding from scratch a (pseudo) Baroque palace is in itself an interesting commentary on the contemporary thirst for "heritage" even if it is not genuinely authentic. Subsections 2.4 and 2.5 of the Charter call for the "retention of the authenticity of heritage places" (2.4) and for infrastructure developments at heritage sites to use local materials while respecting local traditions and styles in architecture.

The third of the six principles deals with the visitor's experience at places of cultural tourism. It contains four subsections each of which gives guidance on ways in which the visitor's experience can be enhanced. It is essential for the economic success of cultural tourism that visitors find a particular experience rewarding, authentic, and well managed. Visitors are usually discerning and well-informed people who will quickly turn elsewhere if their experience of a particular heritage site, practice, or artifact is artificial, disrespectful, or exploitative. They also have myriad needs that vary from person to person and they generally value experiences that offer visitors flexibility and individuality. Subsection 3.2, thus, calls for visitors to be able to pace their visit to a heritage site at their own discretion, while subsection 3.1 calls for visitors to be provided with "high-quality information" on the significance of a particular item of heritage.

The Charter stipulates the various elements of a cultural experience that visitors should be able to expect. They also have responsibilities, though. Successful cultural tourism is able to balance the desire of visitors to experience places, artifacts, and practices of cultural significance with the right of host communities and the interest of all parties in the preservation and conservation of natural and cultural heritage for posterity.

The rights of host communities who are involved in cultural tourism are the focus of principles 4 and 5. In particular, these principles call for the rights of communities to restrict access to sites, cultural practices, and artifacts to be respected. Cultural tourism has a strong universalist element. Western Enlightenment thinking holds that cultural traditions, sites, and practices should be universally and equally accessible to everyone. It rejects the idea of knowledge that can or should be restricted to certain people based on community membership, religious faith, or gender. But more recent ethical debate has led to a realization that Western thinking cannot reasonably be imposed on peoples and communities that do not share its tenets.

Subsection 4.1 deals with the rights of host communities and traditional owners to contribute to management plans, policies, and protocols concerning places of cultural tourism. Making host communities the primary beneficiaries of cultural tourism is at the heart of Principle 5. When well managed, the benefits of cultural tourism can be numerous and substantial. They extend beyond the purely economic and can include employment, educational, intercultural, and intergenerational dividends. Subsection 5.2 even advocates for gender equality in the distribution of benefits that accrue to local communities from cultural tourism. The reinvestment of a proportion of revenues earned from cultural tourism in the protection and conservation of places of significance is the central objective of subsection 5.3.

The interpretation of cultural heritage and its presentation to visitors is a critical element of successful cultural tourism. It may also be an area of debate and controversy. Sometimes the

cultural significance of a site, artifact, or practice may no longer be fully understood. In such cases, interpretation may be largely speculative and it may be difficult to separate fact from fiction and mythology. Recent research may even challenge or contradict long-cherished understandings and interpretations. In other cases, the same site or artifact can have different and even conflicting meanings to different communities. Former battlefields, for example, may represent the site of a famous and nationally important military victory for one community while arousing painful memories of defeat, loss of life, and national subjugation for another community. Sensitive, respectful, and balanced interpretation of such sites is vital if they are to contribute to the peaceful coexistence of communities and nations in our time. These examples all attest to the central role played in cultural tourism by cultural interpreters. Subsections 5.4 and 5.5 of the Charter deal with interpreters and call for them to be drawn from host communities so as to develop skills among community members and to promote interest among local communities in their cultural heritage and its preservation.

The sixth and final of the Charter's principles deals with the protection of natural and cultural heritage in the context of cultural tourism. It calls for controls on excessive visitor numbers at sites of cultural tourism and proposes that host communities encourage visitors to take a wider view of the region in which a particular attraction is located. The subsections also call for host communities to encourage appropriate behavior among visitors by ensuring that the information provided deals with the heritage of a place or community in a responsible fashion.

The International Cultural Tourism Charter is, by dint of its legal status as charter, not an enforceable legal instrument. It sets out principles of good practice but is, in essence, aspirational.

The Charter is narrow in its understanding of cultural tourism. Its primary focus is clearly on cultural and natural heritage sites. Cultural tourism involving intangible heritage, such as performances, ceremonies, and rituals, is not explicitly covered in the Charter. Nor does the Charter deal explicitly with movable cultural artifacts. These features reflect the Charter's own parentage as a document produced by the International Council on Monuments and Sites.

The Charter makes occasional reference to the protection and conservation of natural heritage, but does not make clear the difference between the two.

The Charter is available in English, French, Spanish, Greek, Mandarin, and Dutch and can be accessed via the ICOMOS website at http://www.international.icomos.org/charters.htm.

International Heritage Conservation Principles: Historical Overview

Anja Merbach[1] and Kerstin Stamm[2]

[2]University of Bonn, Berlin, Germany

Introduction

To keep and maintain what we value and to hand it down to future generations is an aspect intrinsic to human development and deeply rooted in all cultures worldwide. Modern times saw the development of the concepts of heritage and conservation, which, as an inseparable part of building and preserving the cultural identity of a group, today have been established as critical elements of national culture. International principles on preservation and conservation try to build a bridge for conservation efforts worldwide and aim to establish a common understanding on what to preserve and how, and more generally, on the meaning of heritage for society as a whole.

Definition

The term "International Principles of Conservation and Preservation" is mostly used to describe internationally recognized and collaboratively developed doctrines and standards relating to the protection, care, and treatment of heritage resources, both movable and immovable (cf. Jokilehto 2002).

Considering the cultural and natural heritage as irreplaceable and precious, the responsibility of all to safeguard the common heritage of mankind and transmit it to future generations "in the full richness of [its] authenticity" constitutes the principal doctrine of the international conservation movement (cf. ICOMOS 1964, *The Venice Charter*, Preamble). In guiding countries and their experts in the practical implementation of this doctrine, international principles of conservation and preservation have been developed over time, all of them basically identifying and defining:

1. The subject of conservation (what)
2. The meaning/content and aim of conservation (why/for whom, the relevance of context)
3. The rules/methods of conservation (how, scientific and technical aspects)

International conservation practice covers a broad range of tangible and intangible subjects, and in its laid down principles, categories such as historic monuments (ICOMOS 1964, *The Venice Charter*, Art. 1) or cultural and natural heritage (UNESCO 1972, *The World Heritage Convention*, Art. 1) are more closely defined. In this respect, conservation practice is restricted to the subjects of conservation identified and defined in the various international agreements. However, definitions keep on widening in their scope and there is international recognition that, principally, every place that is of value to people can be subject of conservation and preservation (Petzet 2005: 8).

The definition of aim and content of conservation is intrinsically connected to the theoretical discourse on "the true meaning" of conservation. This discourse underlies the entire history of the development of (international) conservation principles and, naturally, its arguments shaped their content and meaning over time. Traditionally, the restoration movement employed and propagated the approach that restoration was about bringing back the "ideal" or "true" state of an object or place, based on "objective" and scientific knowledge. Today, there is international consensus that the discipline of conservation/preservation/restoration in general aims to retain a place because it is culturally significant, this cultural significance needing to be defined anew for every place or object (De La Torre 2002: 3; *The Venice Charter*, Art. 1 and Art. 3; Australia ICOMOS 1999, *The Burra Charter*, Art. 2.2). Hence, at the heart of the modern conservation movement, featuring principal protagonists such as John Ruskin (1819–1900), William Morris (1834–1896), or Alois Riegl (1857–1905), lies the concept of

values and the recognition of the relativity of values (Jokilehto 2002: 18, 174–244). According to the *Burra Charter* (ICOMOS 1999, Art. 1.2), the concept of cultural significance can be defined in the following way:

> Cultural significance means aesthetic, historic, scientific, social or spiritual value for past, present or future generations.
>
> Cultural significance is embodied in the place itself, its fabric, setting, use, associations, meanings, records, related places and related objects.
>
> Places may have a range of values for different individuals or groups.

Beyond the doctrines on the subject, content, and aim of conservation, there are principles defining the approaches and methods for retaining a place in its full meaning. The fundamental principle is the concept of authenticity, according to which an object is to be conserved in its authentic "truthful" state, this state being defined within its cultural context and not according to certain objective standards (UNESCO 1994; cf., section "Key Issues/Current Debates"). In order to respect and conserve a place in its full authentic meaning, conservation interventions should change "as much as necessary but as little as possible," giving the principle of "constant care and maintenance" primacy over any other conservation method (*The Venice Charter*, Art. 4; *The Burra Charter*, Art. 1.5, 3.1). There is a variety of terms for the methods or principal measures of conservation, encompassing for instance preservation, maintenance, restoration, renovation, and reconstruction. These different conservation methods are most often formulated as "rules," indicating which method should be best employed, how and under which conditions. A set of definitions is given, for instance, in Art. 1.4–1.8 of *The Burra Charter*, and *The Venice Charter* lays down a multitude of principles or "rules," that is, "Wherever the traditional setting exists, it must be kept" (Art. 6).

Even though the principles in *The Venice Charter* are internationally recognized, conservation methods are understood and used differently in different parts of the world. However, all conservation practice is based on the general principles outlined above and hence grounded in a common understanding of conservation theory and practice as a discipline that aims to preserve what is of value to people (Clark 2010).

Sources of international conservation principles are documents developed and agreed upon within an international discourse and through international collaboration of countries and conservation experts worldwide. In establishing this collaboration, international key organizations for the conservation of the cultural and natural heritage are instrumental.

The International Council on Monuments and Sites (ICOMOS) as the international forum for professional dialogue is the platform on which most of the international charters and guidelines on heritage conservation and preservation are developed. The fundamental conservation guideline is the *International Charter for the Conservation and Restoration of Monuments and Sites* (*The Venice Charter*) from 1964, which was the basis for the so-called *Burra Charter* (*The Australia ICOMOS Charter for Places of Cultural Significance*, 1999), drafted by Australia ICOMOS and highly influential and recognized outside Australia. There are further charters developed by ICOMOS, covering a range of conservation subjects, for example, the *Charter for the Protection and Management of the Archaeological Heritage* (Lausanne 1990). Agreed upon and adopted by expert individuals, charters and the principles expressed by them are legally not binding, yet highly relevant in international heritage discourse. Each country should apply the international principles within the framework of its own culture and legislation.

A legally binding source of international conservation principles are multilateral treaties negotiated on an intergovernmental level. Usually initiated in the international framework of the United Nations Educational, Scientific and Cultural Organization (UNESCO) or, on a European level, in the framework of the Council of Europe, international treaties are agreed upon by the signatory states and put into force after ratification by a certain number of signatory states, as defined in detail in every treaty. The UNESCO *Convention Concerning the Protection of the World Cultural and Natural Heritage* (*The World Heritage Convention*, 1972) is the most well-known and

successful international treaty and the first installing a common protection system for culture and nature (UNESCO World Heritage Centre 2007). Since then, a wide range of international conventions have been drawn up, constituting an important source for international heritage conservation and its principles, including for instance the UNESCO *Convention on the Protection and Promotion of the Diversity of Cultural Expressions* (2005) or the *European Convention on the Protection of the Archaeological Heritage* (Valetta 1992).

Historical Background

Principles of preservation and conservation are nothing permanent, but in continuous development, and so are the associated practices and methods. They very much reflect the time of their conception. Most often, conservation principles evolve as a reaction to major transformations in the sociopolitical, cultural, or economical context of life. The historical perspective on international preservation principles shows that new principles seek to respond or to adapt to new needs. Central concerns or key issues in the field of heritage conservation continue to shift, while the terms that are at the core of preservation principles are regularly redefined.

While the general history of heritage conservation has its roots in antiquity, a development of international preservation principles began only in Modernity, by the end of the nineteenth century. In their combination of political issues, history, social sciences, law, philosophy, ethics, and others, preservation principles are a particularly complex matter. However, as they are by definition a form of international public law, a primary approach to their historical background is through the history of law.

As a matter of fact, international principles are essentially based on the preceding forms of national, communal and local laws for heritage conservation. The earliest documented legal acts of that kind are from Roman law (cf. Poulot 2001) and concern the local protection of moveable and immovable objects which were valued as monuments (cf. Choay 1996). A major advancement in the general development of preservation principles followed in the course of the fourteenth and fifteenth century with numerous edicts and laws passed in various Italian republics which, for the first time, explicitly stated public interest as a motivation for protecting cultural heritage assets. Still, these laws focused mainly on built or material heritage, second most important for the advance in international preservation principles were the consequences of the French Revolution and secularization throughout Europe. The idea of a common, public heritage generated a new form of collective consciousness: the nation (cf. Babelon and Chastel 1994). With an inherent notion of public responsibility for heritage, conservation became increasingly institutionalized, or, in other terms, nationalized: Cultural heritage had finally assumed a fundamental importance for preserving collective cultural identity. The foundation for this understanding of heritage as an expression of collective identity and associated conservation philosophy had been laid by the late eighteenth century's concept of historical time: the insight that any man-made object belongs to a certain time and place, that it cannot be repeated in another (Schmidt 2008), and that it therefore uniquely "represents" its context. By the end of the nineteenth century, heritage conservation had become an essential element in the building of nations and the legal organization of the nation-state (Jokilehto 2002). In this view, the first and foremost preservation principle of protecting national values also entered the first models of international public law, namely, the Hague Conventions of 1899 and 1907, which as laws of war included first paragraphs referring to the special treatment of foreign cultural property in armed conflict, acknowledging thus the essential importance of heritage property for peoples. After the Second World War, these early considerations were finalized in the *Hague Convention on the Protection of Cultural Property in the Event of Armed Conflict* (1954); a second protocol to this convention was added in 1999. Alongside the fundamental principle to protect cultural heritage assets from the danger of violent destruction or loss as in times of war, from the early twentieth

century onwards, the development of international principles for heritage conservation gained momentum. The *Athens Charter on the Restoration of Historic Monuments* (1931) was groundbreaking in this regard because it included a first call for establishing international organizations for restoration on operational and advisory levels. Consequently, in the 1950s and 1960s, a series of international bodies for cultural and natural heritage and for the development and implementation of international preservation standards and principles were founded: the UNESCO in 1946, followed by ICOM (International Council of Museums, 1947), the IUCN (International Union for the Conservation of Nature and Natural Resources, 1948), and ICCROM (International Centre for the Study of the Preservation and Restoration of Cultural Property, 1956), as well as ICOMOS in 1965. The three last-named organizations operate as advisory bodies to the UNESCO. These inter- and nongovernmental institutions and associations deal with educational, legal, and technical issues of conservation from an international to a local level, contributing thereby to the worldwide dissemination and implementation of international preservation principles. With growing international attention for preservation, consequently also the importance of those international public bodies, along with a number of internationally operating private institutions, is growing.

A turning point in understanding cultural heritage as being of international public interest was the *Convention Concerning the Protection of World Cultural and Natural Heritage* (UNESCO 1972), which designated for the first time heritage as universal, concerning all nations alike, that is: humankind (UNESCO World Heritage Centre 2007). Through the *World Heritage Convention*, the concept of a universal, world heritage became codified and the "outstanding universal value" of the heritage protected under its schemes is acknowledged through its protection instrument on an international level, the World Heritage List (*The World Heritage Convention*, Art. 11.2).

Meanwhile, the steady evolution of the definition of heritage contributes to a significant enlargement of the subject of preservation principles. Limited in their origin to historic monuments, international preservation principles gradually were extended, first to other forms of material heritage, such as sites, while subsequent conventions included the protection of historic gardens (*The Florence Charter*, ICOMOS 1981), historic towns, and urban areas (*The Washington Charter*, ICOMOS 1987), as well as the *Protection and Management of Underwater Cultural Heritage* (UNESCO 1996), and of landscapes (*European Convention on Landscapes*, 2000). In accordance with the widened subject of interest, the reach of preservation principles was also enlarged: In addition to protection, international conventions increasingly relate to questions of management, most clearly so in the *International Cultural Tourism Charter* (ICOMOS 1999) *for Managing Tourism at Places of Heritage Significance*. In the year 2004 another crucial turn in understanding the notion of heritage and hence preservation principles became manifest with the UNESCO *Convention for the Safeguarding of Intangible Cultural Heritage* (2003). The *Nara Document on Authenticity* (UNESCO 1994) and in particular the Australia ICOMOS *Charter for the Conservation of Places of Cultural Significance* (*The Burra Charter*, 1999), testified to the primary recognition of the immaterial aspect of the concept of heritage, arguing that it merited equal protection to material heritage. From Europe, one of the latest international preservation principles is the *Council of Europe Framework Convention on the Value of Cultural Heritage for Society* (*The Faro Convention*, 2005). This convention regards the significance of heritage and for the first time provides an understanding of the heritage community, namely, the "people who value specific aspects of cultural heritage which they wish, within the framework of public action, to sustain and transmit to future generations." The constant heritage discourse and the regular revision of central international documents such as *The Burra Charter* and the *Operational Guidelines for the Implementation of the World Heritage Convention* (UNESCO, 2011) ensure an evolution of international conservation principles according to contemporary needs and concepts.

Key Issues/Current Debates

A key issue in international heritage conservation is the role and meaning of values (Avrami et al. 2000; De la Torre 2002; De la Torre et al. 2005; Clark 2006). Conserving what is culturally significant until recently meant expert-defined decisions on the identification and treatment of places worthy to be preserved. There was a focus on values identified and defined by experts, such as historic or scientific value and, in a traditional, Western view, on values attributed to the material fabric of places. Accordingly, the main focus of conservation principles was on technical and scientific rules relating to form, material fabric, and the prevention of change (Clark 2010: 90). With increasing recognition of conservation as a "complex social practice," there is now a democratization of conservation theory and practice: Value categories expand and their relative, ever-changing nature becomes more and more recognized, all of this challenging traditional conservation processes (Avrami et al. 2000: 3). Values being important for the public, such as social value attributed to places – first recognized by the principles of *The Burra Charter* – or intangible concepts of significance, most often employed in non-Western countries, inevitably lead to new perspectives on heritage and its conservation and management, often conflicting with traditional value sets.

Conservation faces the challenge to find approaches towards identifying and negotiating these conflicting sets of values and to integrate the often different objectives towards conservation and its results into holistic conservation processes. Nationally and internationally, the discourse on conservation and its principles is shifting from being focused on preserving places and their fabric to the management and use of heritage (Araoz 2009). How to use the past in the present, as part of sustainable community development and without compromising the tangible places, is one of the key issues of conservation in the twenty-first century and requires a better understanding of the nature of values and their role in conservation.

The prerequisite to perceiving cultural heritage assets as witnesses or historical evidence of the past is the notion of their authenticity, in a general sense their being true and real. Focusing on the documentary function of the monument, as in historical science, the first international preservation principles put the main emphasis on conserving the historic fabric. According to the *Venice Charter* (1964), authenticity was to be preserved by allowing no changes to its "original material," that is, the physical entirety and/or setting of the monument, unless required for its safeguarding, and only to be executed by restoration specialists. This interpretation of authenticity as a (physically) unaltered, historic status became dominant in the course of the following decades, not least because the *Operational Guidelines for the Implementation of the World Heritage Convention* saw authenticity/integrity as conditions for World Heritage nominations, to be evaluated according to the attribute's design, materials, workmanships, or setting. Only in the 1990s was this concept challenged when a revision of the World Heritage Convention criteria led to the Nara conference and the *Nara Document on Authenticity* (UNESCO 1994). This document defines the concept of authenticity as rooted in specific cultural contexts according to which it should be judged; hence, it shifts the focus from the historic, physical fabric to a more comprehensive understanding of the essence of cultural heritage assets. The current debate on "tolerance for change" in conservation practice – where conservative criticism (mis)interprets "tolerance" as a freeway to uncontrolled alteration and destruction, while the term actually implies acceptable variations on a given object, preserving its authenticity, that would hence have to be defined exactly in every single case – illustrates that the contest between these two main concepts continues.

International Perspectives

Naturally, the existence of international preservation principles and the essential international discourse on heritage conservation do not imply that heritage conservation is practiced in the same way

all over the world. First and foremost, there are evident differences in the key subjects of heritage protection according to regional realities and cultural contexts. For example, mountainous regions might be less concerned with underwater heritage or intangible heritage, a minor issue in countries with a traditionally strong focus on built heritage and material fabric. Second, it has been argued that the concept of heritage and its need for preservation is original only to Western thinking but has since then been globalized. Nevertheless, it can be acknowledged that it is through international discourse that international agreements in preservation standards and norms have been established which at present are influencing regional development in heritage preservation (cf. Vinson 2009). More important, it is international exchanges in the theory and practice of heritage preservation that, particularly in the wake of significant anniversaries, produces continuous critique and revision of international documents, hence also of their often limited context and possible imbalances. Finally, while the ongoing development of heritage definitions has brought to light the basically unlimited variety of heritage assets, an international understanding is gradually taking shape that realizes the value of heritage for the individual and for society to be an essential, universal part of human culture; hence, it is the responsibility to protect, and the right to participate in, cultural heritage that need to be universally, internationally promoted.

Future Directions

Sustainable development is the key phrase for all activities relating to the human environment, hence also for conservation of the cultural and natural heritage. Not yet explicitly mentioned in most of the international conventions and charters concerning heritage conservation, the interrelation of heritage and sustainable development is internationally acknowledged and can be defined the following way:

"The protection and conservation of the natural and cultural heritage are a significant contribution to sustainable development." (Para. 6 *Operational Guidelines for the Implementation of the World Heritage Convention;* cf. also: Preamble, Art. 9 and 10 of *The Faro Convention*)

How heritage can be used wisely in order to benefit the sustainable development of our society, be it in economic, social, or environmental terms, is the major challenge ahead for the conservation movement. One important issue in this context, dominating debate and research on heritage and environment, is global climate change and its effects on the material and immaterial heritage (ICOMOS 2008; Long and Smith 2010). Global climate change as defined in Article 1.2 of the *United Nations Framework Convention on Climate Change* (1992) endangers heritage on a global scale and in a variety of ways. According to ICOMOS, the "main climate change parameters affecting cultural heritage are temperature change, atmospheric moisture change, sea level rise, wind, desertification, pollution and biological infestation" (ICOMOS 2008: 194). The effects these parameters have on tangible heritage are starting to be recognized and investigated in detail, and international recommendations on adaptation to climate change developed, emphasizing the relevance of tools such as monitoring, research, preventive maintenance, and training and advocacy with regard to global climate change and risk preparedness (ICOMOS 2007). In fact, there is a focus on the preservation of material fabric and on technical, site-specific approaches to adapt to the threats climate change is posing to buildings and structures. Developing a more comprehensive understanding of climate change as a threat to culture and intangible heritage, in fact to livelihoods, as well as an understanding of "the power of culture" as a tool helping to adapt or even mitigate climate change, will be of growing importance in the future (Long and Smith 2010: 184).

With the growing weight of heritage preservation in international politics, another major issue on the rise is human rights in heritage conservation. Research in political analysis has highlighted the arguably critical potential of heritage as a practice of social oppression and exclusion (Smith 2006; Díaz-Andreu García 2007), and in this context the dominance of Western scholarship

in international heritage conservation has received overdue critique. While the UNESCO *Convention for the Safeguarding of Intangible Cultural Heritage* from 2004 is generally acknowledged as a first important measure to amend this imbalance, as it explicitly relates to the Universal Declaration of Human Rights (United Nations, 1948), the challenge remains of how to reconcile the concept of heritage, defining a collective cultural identity, with fundamental but individual rights. The *Fribourg Declaration on Cultural Rights* is breaking ground here by declaring cultural rights as intrinsic to human rights (*Fribourg Declaration on Cultural Rights*, 2007). Likewise, the *Faro Convention*, that is, the *Council of Europe Framework Convention on the Value of Cultural Heritage for Society* (Council of Europe 2005), is not only "recognizing the need to put people and human values at the center of an enlarged and cross-disciplined concept of cultural heritage" (*Faro Convention*, Preamble), but explicitly states that "rights relating to cultural heritage are inherent in the rights to participate in cultural life, as defined in the Universal Declaration of Human Rights" (*Faro Convention*, Art. 1). In this regard, the growing impetus of critical research on the political aspects of heritage preservation (Smith 2004; Fairclough et al. 2008; Tunbridge 2008) contributes to exploring the potential of heritage preservation principles to employ the fundamental power of cultural heritage for identity and community building, based on the principles of democracy, social justice, and equal rights. Recent studies on the international status quo of cultural rights indicate also their growing importance for international heritage principles (Shaheed 2010).

International Journal of Cultural Property

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Basic Information

The *International Journal of Cultural Property* is an interdisciplinary peer-reviewed journal focused on cultural property and heritage law and policy. It is currently published quarterly by Cambridge University Press and is available worldwide both in print and online. The website is http://journals.cambridge.org/action/displayJournal?jid=JCP, and the editorial office may be reached by email at culturalproperty@cambridge.org.

Major Impact

Founded in 1992 by John Henry Merryman of Stanford Law School as the journal of the International Cultural Property Society, the *IJCP* quickly established itself as the leading journal in the emerging field of art and antiquities law. Over the years, it has expanded its scope to include a full range of topics related to "cultural property" and heritage studies, though with its particular distinction being its continued emphasis

on those subjects' legal and policy dimensions (Bauer 2005). As a result, it enjoys wide readership and regularly features contributions from those in policy arena such as the United Nations Educational Scientific and Cultural Organization (UNESCO), the International Council on Monuments and Sites (ICOMOS), and the World Intellectual Property Organization (WIPO). As of 2010, the *IJCP* has published 17 annual volumes, with a hiatus during 2003 and 2004. Over that time, it had three editors in chief: Norman Palmer (1992–1995), Patty Gerstenblith (1996–2002), and Alexander Bauer (2005–present).

The *IJCP* has published several articles and special issues that have been widely recognized for their importance in the field of cultural heritage. Articles include Lyndel Prott and Patrick O'Keefe's (1991) "'Cultural Heritage' or 'Cultural Property'?," John Henry Merryman's (1994) "A Licit International Trade in Cultural Objects," John Boardman's (2000) "The Elgin Marbles: Matters of Fact and Opinion," and Michael F. Brown's (2005) "Heritage Trouble: Recent Work on the Protection of Intangible Cultural Property." Special issues and sections have included "Cultural Heritage of Indigenous Peoples," edited by Robert K. Paterson and Patrick O'Keefe (1999); "Museums and the Pacific," edited by Haidy Geismar (2008); "Decoding Implications of the Genographic Project for Archaeology and Cultural Heritage," edited by Julie Hollowell and George Nicholas (2009); and "Spoils of War v. Cultural Heritage: The Russian Cultural Property Law in Historical Context," edited by Patricia Kennedy Grimsted (2010).

International Journal of Heritage Studies

Laurajane Smith
School of Archaeology and Anthropology, Australian National University, Canberra, ACT, Australia

Brief Definition of the Topic

Founded in 1994, this is the leading referred interdisciplinary journal in international heritage studies. Published as 12 issues a year (as of 2019), by Routledge, the *International Journal of Heritage Studies* (IJHS) includes original research articles, review articles, short reports or discussion pieces, and book reviews. The remit of the journal is to encourage the development of heritage studies both as an area of academic enquiry and as an area of public policy and practice.

Heritage studies became a recognizable area of academic enquiry during the 1980s. The study of heritage was itself initiated by the surge of national and international policies and legal instruments that were enacted around the globe during the 1960s and 1970s in an attempt to conserve and protect the built environment, archaeological sites, artistic works, and significant material culture as heritage. Although heritage studies developed out of the professional practices concerned with heritage management and architectural and art conservation, heritage studies is not confined only to the development of technical issues and practice. IJHS is dedicated to the theorization of heritage as a cultural phenomenon and aims at fostering international and interdisciplinary debate about the nature and meaning of heritage with particular emphasis on how heritage links to memory, identity, and sense of place.

Thus, the remit of the journal is to publish articles contextualized within the growing field of heritage and museum studies which contribute to debate about the theorization of heritage as cultural, political, and/or social experiences as well as articles that critically address technical, professional, or policy issues (i.e., cultural heritage management). In fostering the development of heritage studies, the journal also supports the development and activities of the Association of Critical Heritage Studies, the inaugural conference for which was held in 2012 at the University of Gothenburg, Sweden.

Contributing authors come not only from the interdisciplinary area of heritage and museum studies but also from the disciplines of geography, history, tourism, sociology, anthropology, law, cultural studies, archaeology, architecture, politics, social psychology, memory studies, and interpretation and design.

The founding editor of the journal was the geographer Peter Howard (1994–2007), then at the University of Plymouth (UK), he was followed by Fiona McLean (2007–2008), then at Glasgow Caledonian University, and the journal has been edited since 2009 by Laurajane Smith (Australian National University). The current book review editors are Ross Wilson (University of Nottingham UK) and Michelle Stefano (Library of Congress, American Folklife Center). The editorial board is made up of academics and practitioners from a range of disciplinary and national contexts. The URL for the journal is https://www.tandfonline.com/toc/rjhs20/current.

International Journal of Historical Archaeology

Charles E. Orser Jr.
Department of Anthropology, New York State Museum, Albany, NY, USA

Brief Definition of the Topic

The *International Journal of Historical Archaeology* is a professional, fully refereed quarterly published in March, June, September, and December. Charles E. Orser, Jr., developed the journal in 1996 in collaboration with Eliot Werner, who was then the anthropology/archaeology editor at Plenum (now Springer).

By the early 1990s, the practice of historical archaeology was expanding throughout the world, but much of the research results were known only to archaeologists working or living within the particular region of the research. In addition, a significant proportion of worldwide research in the field was being conducted as agency-sponsored projects, research that typically includes the preparation of manuscripts of limited distribution. The original plan of the journal was thus to extend the reach of historical archaeology by publishing articles by professional archaeologists throughout the world regardless of their location. The underlying belief was that a broader appreciation of important research taking place outside North America and Western Europe – locations already well served by professional journals – would enormously benefit the discipline by allowing archaeologists to widen the scope of their comparative knowledge.

The journal defines historical archaeology in two ways: (1) as a general method that employs materials from archaeological excavation and textual information in the study of the past and (2) as the use of this multidisciplinary method to examine specifically the post-1500 CE world. Most of the articles published as of this writing conform to the second meaning, but the *IJHA* accepts manuscripts focused on all issues pertinent to contemporary historical archaeology regardless of

temporal focus, provided the author uses textual materials (broadly defined) in some fashion.

International Scientific Committee for Documentation of Cultural Heritage (CIPA)

Mario Santana Quintero
International Scientific Committee for Documentation of Cultural Heritage (CIPA), Ottawa, ON, Canada

Basic Information

CIPA is ICOMOS's (International Council on Monuments and Sites) Scientific Committee for Documentation of Cultural Heritage (CIPA), established in 1968 in collaboration with ISPRS (International Society of Photogrammetry and Remote Sensing). Its web site is at http://cipa.icomos.org/ (Fig. 1).

International Scientific Committee for Documentation of Cultural Heritage (CIPA), Fig. 1 Logo of CIPA

Major Impact

CIPA's main purpose is the improvement of all methods for recording, documentation, and information systems of heritage places, specially through the synergic effects gained by the combination of methods; particularly, the special consideration of digital surveying with all its aspects is an important contribution to recording and perceptual monitoring of cultural heritage, to conservation and restoration of any valuable architectural or other cultural monument, object or site, and as a support to architectural, archaeological, and other art-historical research.

ISPRS and ICOMOS created CIPA because they both believed that a monument can be restored and protected only when it has been fully measured and documented and when its development has been documented again and again, i.e., monitored, with respect to its environment, and stored in proper heritage information and management systems.

CIPA holds an International Symposium every 2 years, either in conjunction with a major conference of the two parent organizations or as a special

CIPA event. Often, accompanying these Symposia are specialist workshops dealing with specific topics. The proceedings of the Symposia are also published, either as a journal or on CD-ROM, and some papers are available through the CIPA web site. CIPA also maintains a discussion list, where the experts associated with CIPA provide advice and information on problems and solutions. It also supports other heritage recording initiatives internationally.

International Slavery Museum

Richard Benjamin
National Museums Liverpool, International Slavery Museum, Liverpool, UK

Introduction

The display galleries at the International Slavery Museum (ISM) opened on August 23, 2007. Not only was 2007 the bicentenary of the Abolition of the Slave Trade Act but also a day designated by UNESCO as Slavery Remembrance Day, the anniversary of an uprising of enslaved Africans on the island of Saint-Domingue (modern Haiti) in 1791. Each year, National Museums Liverpool commemorates Slavery Remembrance Day with a series of events culminating in a traditional libation on the world famous Liverpool waterfront. The day pays homage to the many lives lost as a result of transatlantic slavery; it remembers Liverpool's role as the main British slaving port and also celebrates the survival and development of African Diaspora cultures.

The main objectives of ISM are the following: (1) to inform and help visitors understand the history of transatlantic slavery and the wider issues of freedom and injustice; (2) to challenge preconceptions, prejudice, and ignorance; (3) to encourage visitors to regard transatlantic slavery and its consequences as a shared history with shared responsibility for addressing its legacy in the modern world; and (4) to interpret, in an open

and honest manner, Liverpool's role in the transatlantic slave trade and its impact on the economic and cultural growth of the city.

ISM has three permanent galleries: *Life in West Africa* looks at the area from which the majority of enslaved Africans were stolen and explores Africa's long and complex cultural history; *Enslavement and the Middle Passage* covers the economics of slavery, particularly focusing on the Liverpool merchants that were at the forefront of British involvement, plantation life, and slaving voyages; *Legacy* examines slavery as a modern phenomenon – global inequalities, cultural transformations, racism and discrimination, and the lives and achievements of members of the African Diaspora.

The museum aims to enhance the understanding of the past and how its legacies affect people's daily activities, opportunities, and aspirations. One of the ways in which ISM aims to achieve these goals is by being an active supporter and vehicle of social change, as well as a political campaigner in the field of human rights. Marstine (2006: 2) explains that "Museums are not neutral spaces that speak with one institutional, authoritative voice. Museums are about individuals making subjective choices."

Definition

Terminology can often be problematic when dealing with issues around slavery, such as the use of the word "trade" in transatlantic slave trade. Several commentators believe this excuses the process of enslavement and commoditizes the enslaved Africans. Recent scholarship has also seen a shift from using the name *slaves* to an adjective *enslaved* granting these people an identity, describing their place in society and not reducing them to that position.

Key Issues/Current Debates

African Diaspora Archaeology

ISM demonstrates the value of the archaeology of slavery within museums and how archaeology can speak on behalf of certain (at times forgotten) African Diaspora communities. The museum has participated in several slavery-related archaeological projects. The St. Kitts-Nevis Digital Archaeology Project investigated the lives of enslaved Africans through excavation and interpretation of the material remains they left behind. The project digitized and delivered web information for three eighteenth-century plantations and their "slave" villages: two located on Nevis and the other on St. Kitts. The result is a digital collection of fully searchable archaeological and historical data from multiple sites in the Caribbean that is accessible on the **ISM** website, one of several information portals (http://www.liverpoolmuseums.org.uk/ism/slavery/archaeology/).

The museum also collaborated with archaeologists and the St. Helenan authorities on loaning archaeological material and designing an associated exhibition relating to excavations undertaken in Rupert's Valley, St. Helena, as part of the cultural heritage mitigation for the island's forthcoming airport. The works were carried out by a team of professional archaeologists from the United Kingdom, supported by a number of St. Helenan and non-Saint volunteers. The location formed part of the burial grounds for Africans liberated from slaver ships by the Royal Navy's West Africa Squadron in the mid-nineteenth century. Much of the valley is occupied by these unmarked burial grounds, and the excavations only uncovered a very small proportion of the total number of burials that are known to exist. Prior to this project, no archaeological work had taken place on St. Helena, and so the team broke new ground in every respect. In all, over 300 bodies were excavated, in single graves and from multiple interments. Rupert's Valley contains one of the few graveyards of Africans rescued directly from the slave ships, hence the immense cultural and heritage significance of this remote valley (Pearson et al. 2011).

Museums have to be mindful of the words of Joseph (2011: vii) who notes how activist archaeologists are exploring "the meaningful connections between artefacts from the earth and living communities." One has to put this into context with regard to the archaeology of slavery and its

depiction in a museum. A key point to understand is the value of archaeological research and partnership work for ISM and museums in this field generally. Working with archaeologists whose research covers aspects of the archaeology of slavery aids collection development and object research and offers academic credence to the museum. It offers the opportunity to include material culture relating to sites and individuals which will broaden the understanding of a subject matter and to work with African Diaspora communities in countries where archaeological research is taking place (e.g., St. Kitts and Nevis and St. Helena).

The breadth of archaeological slavery-related material within a museum environment should demonstrate a broad degree of material culture not just from a European perspective, such as goods related to the economics of slavery or implements of enslavement such as physical restraints, whips, and shackles, objects more traditionally associated with slavery. These types of objects are almost overwhelmingly made in Europe, and although interesting and rare themselves, a museum of slavery should, in addition, display and research objects that were either made or owned by enslaved or free and emancipated Africans. Disciplines such as plantation archaeology and African American archaeological studies on lifeways can offer the public a greater awareness of the subject of the African Diaspora and indeed transatlantic slavery and its consequences through related objects (see Singleton 1999).

ISM has a Cultural Transformations section within the Legacy Gallery which shows examples of material culture and cultural traits which might have traveled with Diaspora groups from Africa to locations such as the United States, South America, and the Caribbean. Merriman (1999: 49) notes how there are two methodological approaches to carrying out research on African American lifeways. One recognizes the archaeological patterning of slave sites, using these as markers or signals, whereas the second focuses on "the search for objects with physical or behavioral links to Africa's west coast, has moved beyond the simple transfer of objects and ideas across the Atlantic to a more refined focus which integrates behavior with material culture." In essence, this approach demonstrates how the archaeological record can show that cultural traditions within new environments could be modified, using material at their disposal, rather than simply transferred from Africa.

However, it should be noted that Fennell (2011: 2) observes that there are a host of "theoretical constructs and interpretative frameworks employed in African diaspora archaeology projects and comparative studies in the historical archaeology of sites in Africa." The subject of slavery, both in a historic and modern setting, is expansive and diverse, and although the core of the International Slavery Museum is transatlantic slavery and its legacies, future developments will include facilities to carry out further research in areas currently not covered in great depth in the display galleries but which fall within the museum's remit. This might include slavery and enslavement within prehistory, the classical era, and the Islamic world, "the Gulag" in the former USSR, or the system of indentured labor.

Agency

Agency and ownership need to be carefully considered when designing galleries and planning collection strategies. These discussions were central to the development of one of the more disconcerting yet constructive juxtapositions displayed in the International Slavery Museum: the relationship between the Ku Klux Klan outfit and the Black Achievers Wall. As soon as one walks into the Legacy Gallery, it is difficult not to catch a glimpse of the Black Achievers Wall which has a central, prominent position. It sits close to the Ku Klux Klan outfit but is not dominated by it – achievement versus oppression. This juxtaposition lends itself to the words of Little (2010: 4) who observes, "Our experiences with our histories can leave us both heartened and dismayed, sometimes simultaneously."

In various community consultation sessions arranged prior to the opening of ISM in August 2007, a recurring theme was that the museum had to carefully balance the horror and often visceral presentation of transatlantic slavery with a backdrop of resistance and African and Black

achievement. The Black Achievers Wall shows Black achievement across the arts, sciences, and sporting world, constituting one of several attempts at challenging the visitor not to leave ISM associating African and Black history exclusively with transatlantic slavery or negative perceptions of history. The Black Achievers Wall is intended especially for those visitors of all ages, who know very little about the subject of transatlantic slavery or African history. It is an eclectic portal into African achievement which is often, although not solely, born out of oppression.

The visually emotive Ku Klux Klan exhibit challenges stereotypes, comic caricatures, and romanticized portrayals of the confederacy and the Ku Klux Klan in popular culture, such as *Gone with the Wind* (1939) and *Birth of a Nation* (1915). The fact that the ISM outfit was worn by a Ku Klux Klan member from Orange County in New York State also highlights the fact that this racist organization was nationwide in the United States and not restricted to the southern states.

Future Directions

Within an archaeological framework, there are a number of areas which the museum could develop further, for example, maritime slavery studies and the support of excavations for the next *Henrietta Marie* (see Cottman 1999) by collaborating with projects such as the Slave Wrecks Project (http://www.slavewrecksproject.org/).

There is also an opportunity to expand slavery-related studies and to focus on more African-centered aspects of the narrative such as life in West Africa and the cultural processes which existed prior to encounters between Europeans and Africans and research on contact sites outside of the coastal region, including defensive walls around settlements and shrines or abandoned settlements depopulated by slave raiding. It would also make sense to build on previous archaeological preservation work and research at slave forts such as Cape Coast Castle as well as on free slave settlements and indeed the archaeology of the suppression of slave raiding and trading post abolition – focusing on British-built hinterland forts (see MacEachern 2005: 457–548; Kankpeyeng 2009).

ISM is currently developing one of the world's first permanent collections on the subject of modern slavery, including bonded labor, early and forced marriage, forced labor, slavery by descent, trafficking, and child labor. The focus of this collection is individuals' experiences of being enslaved. The collection, focusing on associated objects, will be used as an interpretive tool to ignite discussion and dialogue about modern slavery and to support campaigns and raise awareness. Moreover, the museum also supports exhibition proposals from external organizations, which actively campaign against all forms of modern racism, discrimination, and slavery.

This new collection stands alongside several other collections. The Diaspora Collection focuses on social history material relating to the Black Diaspora, both historical and modern, from countries that have a link to transatlantic slavery, and in particular the Black presence in the United Kingdom. The curatorial team is particularly interested in Liverpool's social history, actively sourcing collections that reflect the experiences and identities of Liverpool's Black community, their relationship with the city, and the impact of social, political, and economic change on their lives.

The Legacy Collection covers two main areas. Racist memorabilia are a collection of manufactured items that depict racist imagery and racist stereotypes of people of African descent. This material is usually American or British in origin and is often referred to as "Americana" or "Black memorabilia" – not wholly appropriate titles. The Global Inequalities collection reflects the political, economic, and environmental issues associated with global inequalities and fair trade. The domination of world trade by Western markets is considered by many to be a form of economic imperialism, a legacy of the colonial era, and a source of present inequalities. The collection seeks to show these inequalities through case studies and objects from countries such as Haiti, Sierra Leone, Brazil, and Guyana.

It was a steep learning curve for the museum to create one of the few, if not the only, permanent modern slavery collections. The first accessioned

object within the strand was the artwork *Missing* (2007) in 2009 by the artist Rachel Wilberforce. It consists of a series of photographs depicting scenes of a slave trade which still thrives. Photographed in urban and suburban Britain, the images depict sex trafficking and prostitution and the interiors and exteriors of working or derelict flats, brothels, and so-called massage parlors (Wilberforce 2011).

Following this visually evocative work, in 2010 the museum acquired several slavery-related ankle bracelets from the collections of Anti-Slavery International. One of the bracelets was "worn" by a young girl in Niger who was subjected to a form of descent-based slavery. Descent-based slavery occurs in some countries where people are either born into or are descended from a group perceived by other groups as suited for slave labor. The bracelets represent the importance of the work of ISM in developing its collections in modern slavery and campaigning to fight it. The ISM curatorial team understood that it was important to display the ankle bracelets alongside the personal stories of the wearers, to challenge the visitor who believes slavery to be an issue of the past rather than the present. Indeed, there was discussion about referring to the objects as "bracelets" which tends to conjure up images of physical adornment for personal vanity reasons rather than a tool of enslavement. Ultimately, it was decided to use the title given by Anti-Slavery International but to recognize that this subject may need to be addressed at a later stage.

Added to this is the way we might begin to archaeologically frame, among other methodologies, the material culture of modern slavery, which will add a whole new ethical dimension to the archaeology of slavery. Even though enslavement, forced labor, and the quest for freedom are broad thematic classifications, there is the possibility for them to become tangible archaeological strands within a museum of slavery. Modern slavery has social and economic characteristics, which, although difficult, are not unachievable to trace within an archaeological framework.

The conceptual and critical approaches to modern slavery are wide-ranging with the ability to cover a broad spectrum of material culture from personal items of the enslaved individuals (keepsakes, belongings) to related landscapes, such as places of enforced work (brothels, factories) and domestic life in general.

Conclusion

Lowenthal (2003: 187) noted "the fact that the past is no longer present clouds knowledge of it with uncertainty." The statement has less validation when one includes objects of modern slavery. Their meaning is validated by personal interaction and experiences with them; they are most definitely not what Lowenthal calls "*beyond reach*." Not only is the collecting of modern slavery an innovative and challenging strand for the museum, but the related archaeology takes the archaeology of slavery to a new level and opens up new research possibilities that are only now beginning to take shape. Through the development of archaeological research and the displaying of archaeological material, the museum can increase visitors' understanding of the significant role archaeology has to play in slavery studies and museum development generally.

As the museum's modern slavery collection grows and as its partnerships with human rights organizations develop, ISM will have difficult decisions to make about how much and to what we expose the museum's visitors. Allison and Gwaltney (1991: 69) point out, "most visitors are collecting impressions and experiences that will 'make sense' later in conjunction with other experiences and activities in their lives." ISM recognizes the fundamental need for social issues to be challenged and addressed and can become a place where visitors and community members not only "make sense" but "get involved" with subjects and campaigns that ISM champions through its programming and collections.

International Standardization of Fieldwork Payments

S. Matthew Litteral
University of South Florida, Tampa, USA

Introduction

Archaeologists, as employers, engage in a capitalistic system. It is the archaeologist's ethical obligation to negotiate this system responsibly, in a manner informed by anthropological and interdisciplinary perspectives. An international committee of archaeologists should establish a standard for fieldworker payment, in order to prevent social injustice and the exploitation of peripheral communities.

Definition

As archaeological research moves forward in a post-globalized age, the standardization of fieldworker payment has become a more pressing issue of social justice (Linde 2012). Modern communities do not exist in an economic vacuum; rather, they are participants in the global marketplace. Failing to pay locally sourced workers in economically marginalized countries, a standardized international rate perpetuates the structural inequalities inherent in a colonial capitalistic system. Archaeologists, having a unique perspective and understanding of these global systems of power, are fully responsible for the fair treatment of their laborers. The creation of an internationally accepted standard for fieldworker payment would prevent the economic exploitation of communities by replacing the current system in which wages may be arbitrarily established by the individual archaeologist.

Historical Background

Since the dawn of archaeological research, archaeologists have employed local laborers to assist in the excavation process. Historically, this was a purely practical and economic choice, largely due to the budget constraints under which archaeology is conducted. Hiring cheap, locally sourced labor saved Western archaeologists abroad both time and money. However, in recent years the employment of local fieldworkers has taken on the dual purpose of community engagement and public outreach. Commissioning local labor involves the community in the archaeological process and promotes the

reciprocal flow of information between the archaeologist and the public (Overholtzer 2015).

Key Issues/Current Debates

One argument against the international standardization of fieldworker payment posits that offering a pay rate deemed fit by Western standards will upset the delicate economic balance of peripheral communities. A sudden influx of wealth into a poor community may have serious impacts on the inhabitant's daily lives. However, by examining the issue on a more personal level, as a transaction between archaeologist and employee, the ethical course of action becomes evident. Paying a locally sourced laborer less than a Westerner for the same work is an injustice with deep roots in the colonial history of the world and of the discipline itself. Archaeology was originally done by those who were privileged in the global system of power. These early archaeologists often conducted research in countries impacted by colonial exploitation. Archaeologists today should challenge the methodologies of the disciplines colonial past. It is also important to note that even the most marginalized of peripheral communities does not exist in an economic vacuum, but actively participates in the global market. Communities are not in a state of peaceful homeostasis until a disruptive archaeologist comes along to offer profitable employment.

International Perspectives

Archaeologists in the USA are grappling with issues of fair payment (McGuire and Walker 1999). Archaeological unions, such as the United Archaeological Field Technicians and Unite Archaeology Ireland, have been formed by workers in the USA and Ireland. Members of these labor unions demand a living wage for their work. However, there are no international unions to demand a fair wage for all fieldworkers. Considering the complicated issue of fair payment within the USA, it is not surprising that little effort has been made toward regulating the wages offered to laborers hired abroad.

Future Directions

The allocation of fair payment should be addressed in the budgeting stages of every project in which local laborers will be employed. Providing a standard pay rate to all fieldworkers, regardless of nationality, would have a lasting impact on the discipline. The shift in resource allocation may mean scaling back ambitious projects abroad, but it is essential to the promotion of cross-cultural equality. The standard for payment should be established by an international committee of archaeologists. Archaeologists must make the fair treatment of locally sourced workers a top priority, rather than focusing solely on individual research goals. Archaeologists are stewards of cultural heritage, and it is this living population that gives archaeological research meaning and relevance.

I

International Symposium on Archaeometry

Yannis Maniatis
Laboratory of Archaeometry, Institute of Nanoscience and Nanomaterials
N.C.S.R. Demokritos, Attiki, Greece

Basic Information

The International Symposium on Archaeometry (ISA) is a biennial meeting organized to promote the development and use of scientific techniques in order to extract archaeological and historical information from the cultural heritage and the paleoenvironment. It involves all natural sciences and all types of objects and materials related to human activity. ISA's website is at http://www.ims.demokritos.gr/ISA/.

The beginning of ISA can be retraced as early as the 1960s, when the applications of natural sciences in archaeology started to gain more and more importance. While, during the early years, the main focus of the meetings was on geophysical prospection methods of archaeological sites, now all topics in the field of archaeological sciences are covered. Such topics include characterization of inorganic and organic materials, objects and monuments for the identification of provenance and technology, absolute dating, paleoenvironment and paleoclimate investigations, biomaterials and bioarchaeology, prospection and field archaeology, etc. The meeting is usually organized as a 5-day conference presenting sessions on standard topics as well as special theme sessions on selected specific topics. Parallel sessions are avoided for the sake of the interdisciplinary character of the symposium and the need of all participants to be informed on the status of the research in all aspects of archaeological sciences. A very important aspect of the symposium is the poster sessions, which attract the largest number of papers and which generate ample discussion during the specially designed long poster sessions and during the breaks.

Two prizes are offered in every conference for the two best student posters, named *Martin Aitken* prizes after the founder and the first chairman of the symposium. Additional prizes for best student posters are also offered by the international Society of Archaeological Sciences (SAS), named *R. E. Taylor* prizes. More prizes are occasionally offered by different Societies.

The subjects covered by the symposium are generally grouped in the following topics which form the regular sessions in which both oral and poster papers are presented:

Technology and Provenance I (stone, plaster, and pigments).
Technology and Provenance II (ceramics, glazes, glass, and all vitreous materials).
Technology and Provenance III (metals and metallurgical ceramics).
Archaeochronometry (dating techniques, dating and interpretation strategies, cultural phase analysis, etc.)
Biomaterials and Bioarchaeology (DNA, human diet, health, mobility, demography, organic residues, zooarchaeology, archaeobotany, etc.)
Remote Sensing, Geophysical Prospection, and Field Archaeology (All kind of techniques applied to study archaeological sites from the surface, sampling, field walking strategies, site monitoring, in situ observations, etc.)
Occasionally *Integrated Site Studies*, designed for archaeologists reporting combined archaeological and scientific results and interpretation of excavation data, materials, and paleoenvironmental information are presented, either by invitation or by participants initiative.
Special theme sessions are also organized in every venue on subjects that reflect recent trends in the field of Archaeometry or related to particular interests in the region or country where the symposium takes place.
Special sub-sessions or combined sessions are frequently introduced and different emphasis may be given to one or more of the above sessions from venue to venue.

The submitted abstracts are reviewed by a board of international convenors to confirm that

they are within the scope of the conference and also to be assigned as oral or poster presentation according to the nature and extent of research, subject, and general interest. Papers that deal with weathering and deterioration of archaeological objects or monuments are welcome, provided they are relevant to one of the main themes of the symposium.

The symposium is usually attended by an international audience of several hundred scholars from diverse fields, such as physics, chemistry, materials science, geology, biology, conservation science, computer science, archaeology, anthropology, art history. Since the 1980s, the symposium is taking place in an alternating mode at locations in Europe and in the Americas organized by respective local organizing committees. This mode may change if there is a decision for a venue in a third continent.

In order to ensure the continuity and maintain the standards, the organization is managed by the Symposium *Standing Committee* composed of past meeting organizers. The first Chairman of the S.C. was Martin J. Aitken (1961–1986) of Oxford University who was succeeded by Michael S. Tite (1986–2004) also from Oxford University. Since 2004, the Standing Committee is chaired by Yannis Maniatis of National Centre for Scientific Research "Demokritos," Athens (Fig. 1).

Martin Aitken passed away on 13 June 2017 at the age of 95.

The official numbering of the symposium was introduced by I. Scollar, the organizer of the Bonn meeting in 1978. Since his area of expertise was magnetic surveying, he started the sequence with the London meeting on "Prospection in Archaeology by Geophysical Methods" in 1961. During the early years, the symposium was focused exclusively on archaeological prospection using geophysical methods. After the first meeting in London the symposium was organized in the following years at the Research Laboratory for Archaeology and the History of Art (RLAHA) at the University of Oxford. It was initially designed as a 1-day user meeting for archaeologists using proton gradiometers for prospection. In 1969 the scope of the symposium was extended to other subjects apart from archaeological prospection. The name was accordingly changed to "Symposium on Archaeometry and Archaeological Prospection." With a larger program, the symposium was expanded to a 2-day meeting in 1970 and to a 3- to 4-day meeting during the following years. In

International Symposium on Archaeometry, Fig. 1 *ISA, Leuven 29 May 2012*: Reception for the celebration of 50 years of ISA. From right: Patrick Degryse (Local Organizer), Martin J. Aitken (First Chairman of ISA), Michael S. Tite (Second Chairman of ISA), and Yannis Maniatis (Present Chairman of ISA)

1976, the symposium left RLAHA in Oxford, its constant place until then, and started its everlasting journey across the world. Its first stop in 1976 was at the University of Edinburgh which was the hosting institution. Since 1980, the official name of the meeting is *International Symposium on Archaeometry*. Usually, it is hosted in a kind of alternating mode either in Europe or in the Americas, and it comprises a 5-day program, including oral presentations and poster sessions. From 1984, the symposium is organized on a biennial base.

In May 2012, during the 39th meeting at Leuven, the Symposium celebrated its 50 years anniversary (Fig. 1).

For an account of all the places and meetings at which the Symposium was organized up to now, the Symposium was organized visit the official ISA's website at http://www.ims.demokritos.gr/ISA/.

Major Impact

ISA is a unique symposium as it provides the only international forum for all activities in Archaeological Sciences, both individually and integrated. In this conference, one can meet experts and learn of their research in dating, geophysical methods, field studies, palaeoenvironment, biomaterials, ceramics, glass, vitreous, metals, lithics, plasters, pigments, textiles, paper, and so on. New inventions of techniques and novel applications targeting specific archaeological problems are presented. The accumulated information on archaeological objects and materials is compiled and presented in a unified way in order to complete the history of mankind and fill in the gaps in the human history and culture.

Therefore, ISA with its unique character and the fact that is organized alternatively in Europe and the Americas has a global impact on Archaeological Sciences and consequently on archaeology. This impact will be further enhanced in the near future as it has been decided by the Standing Committee to include in future symposia special sessions on global issues relating to major changes and developments in human behavior on a universal level.

Internet Use for Archaeological Education

João Carlos Moreno de Sousa
Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Introduction

Although there is some variety between archaeologists' definitions of Archaeology, most of them agree it is a science that studies material vestiges and that it aims to understand the humanity (see "▶ Archaeology: Definition"). However, archaeology is still completely unknown among a great part of general public. On the other side, some of the people who have ever heard about archeology at least once in their lives still relate it to dinosaurs or some fictional media that, even with no intention, distorts the public understanding related to real life archaeology. Journalistic media still confuses archaeology with paleontology and/or relate it to amateurs and sensationalistic studies of the past. Because of that, some archaeologists are always concerned about providing archaeological learning to the general public (see "▶ "Public" and Archaeology").

Actually, one of the scientific research goals is to transmit knowledge about produced data to other research studies and to the general public as well. Researchers all over the world diffuse this knowledge, most of the times, by scientific publication as articles and books. Unfortunately, a big part of these publications are not presented to the general public in an accessible language, presenting terms and concepts that most of the public never heard about, or discussing subjects in a very specific context. These publications are difficult for the general public, and most of the times people may lose interest in reading them. Another factor interfering on public interest is the absence of open access to some of these publications, which are usually restricted to academics. It is notable how difficult it is to encourage the public to consume these materials; therefore, researchers are always discussing ways of doing public archaeology (see ▶ "Cultural Heritage Outreach"). The main question after all is about what is the best way of providing archaeological knowledge to the public in the modern world.

Researchers interested in providing scientific knowledge for the general public have followed two main guidelines: using simple language and providing free access to scientific publications. Researchers are increasing their understanding over the importance of providing scientific knowledge, since science is made, at least partially, because of (or as a response to) a nonacademic public interest, as well as to solve problems affecting all the society.

Internet is being used now as a powerful tool for a worldwide diffusion of this scientific knowledge, as well as providing access to scientific publications. In other words, Internet is now being used for scientific education, and archaeology is part of it.

Definition

With the increase of Internet use around the world, information gained a potential for transmission never seen before, breaking social, economics, and mostly geographic barriers. People are using Internet not just with computers, but also with mobile phones, tablets, televisions, and some other modern devices. Internet is turning into the major source of information for a lot of people around the world and, in this sense, it is easy to think about how big is the potential for scientific education and learning using online methods. Following this trend, archaeological education through the Internet is also a possible reality.

Internet use for archaeological education, or **online archaeological education,** is basically a way to provide archaeological knowledge through the Internet, reaching any kind of people, academics or not. In this sense, the Internet use for archaeological education may be understood as a type of public archaeology, or even collaborative

archaeology (see ▶ "Service Learning and Public Archaeology" and ▶ "Public Education and Archaeology: Disciplining Through Education"). And because it uses digital methods online, it may even be understood as a kind of digital archaeology.

Historical Background

We do not have to go so far in the past to build a historical background about the Internet use for archaeological education, since archaeology and Internet are connected since late 1990s. Some of the most known online archaeological education projects ever done are still being carried out and may be considered pioneers in the subject. It is a relatively recent phenomenon, which has been done by very few people around the world, making us to believe that the online archeology education history is still in its beginning.

Most of the collaborators making use of the Internet for archaeological education are online magazines or websites contributors with some experience in archaeology, or even scientific journalists specialized in archaeology, heritage, and history subjects. The most known examples of Internet use for archaeological education are online magazines. Some of the most popular websites around the world used by general public for archaeological learning are *Nature* (n.d.), *National Geographic* (1996), and *Heritage Daily* (2011), for example. They are not just very popular magazines around the world, but they also have open access to archaeology sections with lots of articles in their websites. As the articles are written by experts, they provide a trustful basic knowledge about the subjects, also referring to the original publications and researchers that the articles relate to.

Another example of online archaeological education website is *Thought.co* (2017). It has contributors from a large diversity of academic areas, including archaeology. The Archaeology section includes a great number of articles. The major difference of the online magazines from *Thought.co* is that the magazines mostly present archaeology news, interviews, and reports about the subject, while *Thought.co* also presents articles aiming to educate people from the basics, with information from a variety of categories. The website informs about research studies presented all over the world, while also including articles aiming to educate people about what is archaeology, what to consider before choosing a fieldschool, why to preserve heritage and even articles about archaeology law, methods and techniques, and a dictionary. Just like in the case of the online magazines, *Thought.co* articles are written by experts and always refer to original academic publications. Because of the website proposal of educating people, it has a potential of being a primary source of archaeological content to the general public, as well as to archaeology students, since their articles refer to academic publications, being occasionally used as a primary source.

Many of the archaeology research institutes around the world also present news and/or education sections in their websites, mostly providing online education about the research studies carried out by themselves or even by other groups in their countries, sharing very important archaeology news. These institutional website articles are most of the times written by experts in archaeology, which includes archaeologists as well. The archaeology section of *Smithsonian Magazine* website (2005) is an example of that. The *Archaeology Magazine* (2008) website from the Archaeological Institute of America has an online version too, as well as a printed version, with original articles and brief reports about works published in other online magazines, including the links to the original academic articles. The site has a strategy of gathering in the same place articles published in different magazines, turning it into a tool that can be used as a primary source for archaeological content.

There are some websites carried out by experts and academics themselves, with no funding support and nonprofit objectives, aiming just to educate people about archaeological subject. These websites usually use free blogging server services to host their websites. In the last years, The *Archaeology News Network* (Georgopoulos 2010) is doing it, publishing and gathering articles from other international sources together in the same place. Following this path, we can also mention the Archaeological Legacy Institute that has a website entitled *The Archaeology* Channel

(1999) aiming to nurture and bring widespread attention to the human cultural heritage.

Finally, we have the most largely known educational system applied online: The courses. A great number of institutions are providing online courses on a variety of archaeological subjects, directed both to academic students and to the general public. An example of a nonprofit course designed for general public is the Massive Open Online Courses (MOOCs), created in 2008. According to the *MOOC List* website (2016, February 29), there were 18 different archaeology MOOCs produced since 2014 to July 2018.

These are just some worldwide relevant examples of what has been done until the middle of 2010s. Internet has been largely used in the last years as a tool for publishing and sharing scientific articles, books, and other types of research studies results. However, the Internet use for archeological education of the general public is not so largely used as seen for academic purposes. One of the reasons may be the fact that the Internet only started to be largely used by the general public in the last decades, mostly by younger people. On the other side, the older researchers who did not make use of the Internet for years or decades during academic life have few, or none, experience in the online methods and techniques. With the increase of the Internet use by archaeologists, and because Internet is popularly recognized as a powerful tool for disseminating information, it is expected that the online archaeological education projects will increase in number in a near future.

Key Issues/Current Debates

There are two main key issues when talking about the Internet use for archaeological education: how to provide knowledge and which knowledge should be provided. But before discussing these issues, an important thing about online education must be clear: basic computer and digital knowledge and experience are necessary.

Some specific digital techniques are very complex, even for people who use Internet every time. It must be clear that the Internet use for education projects requires at least one person with enough technical knowledge and experience in digital materials production. Obviously, there is a variety of online approaches that can be applied using easy techniques.

Today, the most efficient way of providing online open access to scientific information is developing and managing Internet websites and/or digital software. Because they are less complex to manage and develop most of the times, websites are the most widely online tool used for archaeological education.

How to Provide Online Archaeological Education

Academic Archaeological Education

Online regular academic archaeological education became common in the last years. Online courses (a.k.a.: e-learning, cyber schools, distance learning) are examples of how one can undertake online academic education, a new method of learning that is benefiting students from all over the world (see ▶ "Heritage and Higher Education"). Considering that people can get more motivated studying in their native language, courses applied in different language versions could be an advantage (Barak et al. 2016). Besides that, the inclusion of students with any problems avoiding them to participate in regular classroom courses is another advantage, such as students from places with the absence, or poor quality, of local archaeology education (Kotoua et al. 2015), parents that still need to take care of their kids, or even students with autism disorder (Satterfield et al. 2015).

Journalistic Media

One of the most efficient ways of reaching the general public is through journalistic media, since it is the main source for public information, having an abundant online content that includes archaeology news (see ▶ "Media and Archaeology"). Despite that, most of these media do not sufficiently inform about archaeological subjects from around the world. However, as was mentioned before, some of them have a journalistic team interested in scientific outreach, including professionals with experience in different science areas. These professionals, mostly the archaeology experts, are the best online diffusers of archaeological knowledge, since they have more

experience collecting scientific data from publications, or even from the researchers themselves, delivering them to the public using a simple language without modifying the original information. Any researcher having the intent of diffusing their discoveries, ideas, or opinions to the public is able to contact these professionals (see ▶ "Preserving Heritage: The Role of the Media").

Unfortunately, just a small number of the biggest and more famous journalistic media have a scientific outreach team. Researchers may still contact the smallest vehicles, like the local or regional ones, if they want to publish something, although it is not rare to see journalists contacting researchers in search of new material. Fearing the possibility of spreading mistaken information, some researchers may choose to publish their ideas in their own pages or institutional websites instead of contacting journalists with no experience in scientific outreach.

Archaeology Specialized Websites and Webpages

Online archaeological education websites appeared in the last years, contributing with very good quality materials, even though most of them are made by people with no journalistic experience. The reason for that is the archaeological experience of the administrators and contributors, mostly composed by professional archaeologists, students, or other people directly related to archaeology.

One advantage of having archaeologists as administrators of specialized websites is to escape from the traditional journalistic ways of sharing information. Some media are known as being sensationalists, aiming not to educate people, but to reach more public attention and profit. In these cases, archaeology subject materials may be full of irrelevant or biased information. Managing their own websites, archaeologists are free to communicate directly to the public with none or very few mistakes. On the other hand, no experience in dealing with the general public, or even with digital systems, can become a problem in producing something interesting enough to the public. In that case, learning with other people working with online archaeology education is a good way to solve this issue and find the best forms of attracting people's attention.

Another good thing of these websites is to allow the public to be in touch with the researchers through their email or comment sections, being able to ask questions or even sharing relevant ideas and knowledge.

The existence of some barriers as lack of funds or available time turns it difficult for some researchers to work with online education. Since free online servers are available to develop a website, money is not the biggest problem. Researchers cannot stop their jobs for a nonprofit work, unless it is possible to get some funding or organize a volunteer team to manage and contribute with the website. In this case, everyone can collaborate without taking too much time from their main activities. A second option would be using the scientific outreach team or educative channel from their institution websites, where they can count with experts to make a high quality outreach, costing less time and energy.

Online Social Networks

Academic social networks as Research Gate (2008) and Academia (2008) are used as a way of sharing academic publications and providing open access to previously published articles, which were available only in the traditional printed forms in libraries, institutional subscriptions, or reprint requests. Since these academic social networks do not reach the general public, it is necessary to adapt to the most popular social networks, sharing the information in ways these websites allow us to do.

Some worldwide popular social networks from early and mid-2010s are *Facebook*, *Twitter*, and *Instagram*, for example, where a variety of media can republish and advertise content through their social pages. As open access channels with a vast and global popularity, they are used as an important source of directed information. Social network pages directly related to the official archaeology websites may increase public interest, mostly because of the possibility to publish links of the original materials. It is also possible to produce original and exclusive materials in these social networks.

Audiovisual Production

One of the biggest worldwide phenomena from the last years is the open access to audiovisual content production. As a result of that, some of these audiovisual producers, including some archaeologists, are using Internet to provide scientific content. Internet allows us to reproduce audiovisual content that have been broadcasted by other media, since it follows the legal regulations for copyrights. Some contents were already produced to Internet as the primary reproducer as well.

The most famous kind of audiovisual production for scientific education is probably the documentary, since we see a variety of them on television for decades. Documentaries cannot only be produced for television transmission but for the Internet as well. In archaeology, audiovisual reports are also common, produced not just by journalistic media for the Internet but also by audiovisual production teams from research or funding institutions.

Another popular way of producing audiovisual material is through interviews with professionals of specific areas, being an excellent way of learning and also a trustful source for reference for everyone.

Within this decade, some untraditional methods of producing audiovisual materials appeared in the Internet. The vlogs, for example, are mostly independent productions where a person talks directly to the camera – the public – in a very informal and, sometimes, even humored manner. This kind of production is a good way of attracting the public, mostly young people, because it allows people to use a funny and irreverent way to reproduce information. Besides that, if the information is transmitted by professors, scientists, or experts, they are considered to be really trustful by the public.

Finally, one last kind of audiovisual production with increasing popularity is the online courses. Although they are not as interactive as the regular ones, it turned to be an excellent alternative for students who cannot attend the regular classes, helping to reach different people from all over the world. Obviously, online courses do not need to be restricted to audiovisual lessons and may also provide digital reading and other kinds of digital content as well.

The major advantage of online audiovisual productions, in comparison to other media, is that the public can access the content at any time and wherever they want. Independent or academic funded productions are mostly free to produce the materials in the way the producers think it is right, not concerning about the length limits for the production or other traditional journalistic restrictions or editions, providing complete relevant information without having to cut scenes.

What Archaeological Knowledge May/Should Be Provided

Here we present some examples of knowledge that may or should be provided by archaeologists, not just for other archaeologists and students, but for the general public as well.

Scientific Publications

It is not common for the general public to read scientific publications; however, they represent the entire academic work for students and researchers, being the main source of scientific knowledge. Besides their big importance for science, not everyone has open access to all of them. Because the open access issue is not solved yet, one of the things online archaeology education contributors may provide is a list of books, journals, and other scientific publications with open access. These lists could focus on regional or national publications, or on specific subjects, being used as a primary source for content.

Archaeological Research Studies Outreach

The research and its results outreach is, or should be, one of the biggest objectives of researchers, since they are not done for academic purposes only, but for the interest of the society as well. Because most of people are not able or interested in reading scientific publications, archaeologists should provide them in a different manner, using online open access means and simpler language. Illustrations, summary texts, maps, videos, and other things can all be used. The most important thing is always focusing on the importance of the research and results, as well as justifying the contributions of it to the world.

Basic Archaeology Knowledge Outreach

Providing information using a simple language is the best way to succeed in transmitting basic knowledge. Simple language can be used to produce articles aiming to educate people on the basic archaeological knowledge, like what archaeology is, what are its disciplines, what is an archaeological site or vestige, how archaeologists excavate and analyze things, as well as any other information archaeologists may consider relevant.

Fiction, Pseudoarchaeology and Amateur Archaeology

It is not rare for people to confuse archaeology with paleontology, or also to be fascinated about archaeology while believing in fictional, fake, or even amateur information. Sometimes, providing the basic knowledge about archaeology may not be enough. Articles that make people aware of what scientifically trustful information is and what is right and wrong in fiction may change people's point of view in a good way (see ▶ "Popular Culture and Archaeology").

Making Archaeologists-Public Contact

Internet can provide ways for archaeologists to talk directly to the public, and the public could also talk directly to archaeologists in the same way. With online contact, as through e-mails, comments sections on websites/pages, or even online chatting, people are able to learn more. The public would even be capable of helping contributors with future plans through comments, critics, and compliments.

A second advantage of the Internet is also the possibility of learning with the public about their regional or local archaeology knowledge. Sometimes people would love to share information about an archaeological site or artifact they found, but most of the times they do not know who they should talk to. Considering that in some cases archaeologists would be very interested in people's findings, the approximation between both would be a good approach.

Finally, helping people in a private way about their personal wishes of being a future archaeologist, advising about how to become an archaeologist in their countries, and also sharing some tips about universities or research subjects would encourage more people to enter in the field.

Archaeological Heritage, Ethics, and Law

The most important knowledge archaeologists should provide is about the importance of the archaeological heritage for science and societies (see ▶ "Heritage Values and Education" and ▶ "Heritage and Society"). An educated people would probably have more respect with heritage, with the desire to preserve it too (see ▶ "Cultural Heritage and the Public"). However, people would like to learn about ethics and laws of their country or region concerning archaeological heritage. Therefore, archaeologists may provide the basic knowledge about national or regional laws (see ▶ "Cultural Heritage Management: International Practice and Regional Applications" and ▶ "Legislation in Archaeology: Overview and Introduction"), as well as advices of what people could do to help preserve the heritage or in case they find archaeological sites and artifacts. Online contributors could also share a compiled material including all the legal documents of their country and region concerning the archaeological heritage.

Archaeological Museums, Artifacts, and Sites

Museums and archaeological sites are the places where public is able to have a direct contact with archaeological vestiges, considered as the primary means for public archaeological education. Internet can be a great ally in sharing information about the research studies carried out by museums, about expositions, archaeological sites open for tourist visits, as well as museums and sites locations. Contributors could also provide lists of archaeological museums and sites.

Sometimes just indicating where these museums and sites are located may not be enough, considering that many people could not be able to travel and visit them. In this sense, an increasing recent approach are the virtual museums, with photo galleries, maps, 3d images, and other digital technologies, as virtual reality, with a big potential for archaeological-related information diffusion (see ▶ "Cultural Heritage in the Digital Age").

The open access to virtual 3D reconstructions of sites and artifacts would probably increase the interest of people about archaeology.

Academic Archaeological Information

One of the most desired information by the public interested in archeology is related to the high education and professionalization process. Even though some people do not know exactly what archaeology is, they still want to be archaeologists in the future or, if not, they just want to learn about the subject in universities courses.

A simple and effective way of helping people find archaeological higher education is providing online information about archaeology undergraduation and (post)graduation courses, like lists of courses in different countries. Also, it is important that archaeologists and online education contributors give support to everyone interested in becoming an archaeologist, mostly the ones showing a lot of interest, which may prove to be great archaeology colleagues. Giving information about open courses is very important as well, once they may encourage people to search for higher education courses.

Events

Not just open courses may encourage people, but some events as well, like congresses, symposiums, workshops, lectures, etc. Online information about these events is important too, and they may be provided as calendars. Online contributors may elaborate these calendars focusing on regional events, or also about thematic events (e.g., Calendar of zooarchaeology or lithics events). Most of the events have, now, official websites or webpages that may be linked within the calendar.

Fieldschools and Internships

Calendars are very useful for organizing travels, and it is also the case for events, fieldschools, and universities internships. This is a major interest of people engaged in archaeology and related sciences, once they are looking for more learning and practical experience opportunities. Fieldwork coordinators and other archaeologists are usually looking for people to help them in their projects as volunteers. Providing information about fieldschools and internships can contribute with archaeological education and to encourage new archaeologists.

International Perspectives

With all that exposed, it is possible to notice that a great variety of information can be available in the Internet. We just mentioned some of the most common online sources of information about archaeology. Brazil is an example of country following these perspectives. Besides Brazilian people access international sources, they rather access their own sources, mostly because of the language. The most known sources we mentioned before are all in English and it gets difficult for non-English speakers to follow these sources. So it is interesting for archaeologists around the world to provide information in their native language as well. Thinking about that, Brazilian archaeologists started making use of Internet for archaeological education in a variety of ways during the middle 2010s.

For example, *Arqueologia e Pré-História* website (Moreno de Sousa 2013) aims to educate people by sharing articles about specific subjects and worldwide research studies in a simple language, as well as information about Brazilian museums, archaeological sites, events, open courses, higher education, heritage related law, fieldschools, etc. The website is having an increasing popularity (Fig. 1) through the help of the online social networks, sharing even more information with exclusive material. This popularity is resulting in a positive public return, with people providing information about archaeological findings and asking for advices about archaeological higher education. The website contributors are frequently being invited by schools and public agencies to provide lectures and courses for students and other local citizens.

The same is happening to *Arqueologia Egípcia* (Costa 2008), an Ancient Egypt specialized website that is becoming very popular in the

Internet Use for Archaeological Education, Fig. 1 Number of visits of *Arqueologia e Pré-História* website (Brazil). Statistics from May 2013 to April 2018

country, not just by the administrator efforts, but also as a result of the popularity of the subject. Besides Egyptian archaeology, the website also provides a big variety of archaeological knowledge, making people learn even more than they would expect. As a result of the contributor efforts, with very positive return until now, the administrator also offers lectures and publishes books. More recently, the author has also adopted the vlog type of scientific popularity (Costa 2013) and her videos reached more than 775,000 views until July 2018.

Another volunteer work in Brazilian online archaeological education is *Arqueologia em Ação* project (2013). The project aims to produce video interviews with archaeologists from everywhere in the world about their research studies or some specific archaeological subject they have experience in. The lack of funding and dependence on volunteers time results in a slow increase of the audiovisual material quality, although they have a very positive return from the public. School and university professors, for example, are using the project videos in their classes to teach about archaeology subjects. From May 2013 to Mid-2018, the videos reached more than 28,000 views.

These kinds of nonprofit projects for online archaeological education are becoming very popular among Brazilian archaeology companies as well. The *Contexto's Live* project (2015–2016), for example, was part of a company's public archaeology program, and it has the intention of transmitting online live lectures to the general public, while providing posterior open access to them.

In Brazil, as well is in other countries, archaeology companies must, legally, provide public free education for the locals within the cities they are carrying out archaeological projects. However, Online Archaeological Education is a very efficient approach not just for locals but for everyone with Internet access in any part of the world, as *Contexto's Live* has proved. By this approach people are able not just to learn about archaeology, but about the companies' projects and results as well.

Future Directions

It is important to notice that the higher is the volume and variety of online archaeological knowledge available to the public, the higher is the public interest in the subject. The more the public is getting interested, the more the public become aware of the cultural heritage importance and the more active is the public engagement. It is also important to notice that some people want to know about their local archaeological activities and learn about the importance of it for them. Once the public is aware of this, they tend to respect and collaborate with archaeologists.

That being said, it is not hard to assume how big and important can be the impact of Internet use for archaeological education on societies. So, for the near future, archaeologists should not just discuss how and what to provide as archaeological knowledge to the public, but also to ask why not to carry out online archaeology education projects? The digital world has arrived and archaeologists, besides looking at the past, must also look at their future directions on educating people. Archaeologists and online contributors must be aware that the modern technologies are making it able to innovate educational projects around the world. And soon new ways of online educating might appear and became popular as well.

Internet, Archaeology of the

Paul Graves-Brown
Llanelli, Carmarthenshire, UK

Introduction

By the time you read this, it will be out of date – a fundamental issue when attempting to study the archaeology of the Internet. Readers of Ceruzzi's (1986) contribution to *Imagining Tomorrow* would have been amused by its account of the late 1940s, when experts seriously believed that there would never be more than ten computers in the United States. Yet Ceruzzi himself had no inkling of the World Wide Web (which we now often refer to as just "the Internet") that would emerge in embryo only three years later. William Gibson (2012) notes the error in his Sprawl novels of the 1980s which coined the term "cyberspace" – there is no mention in them of cellular phones. Similarly, the account of the archaeology of the Internet in Graves-Brown (2009) is also out of date.

The "Internet" is amorphous and ephemeral. If we considered it in ruination, as some future archaeologist might do, it would consist of a mass of cables, computers, satellites, manuals, and other artifacts, where any system would have to be inferred (Cubitt Forthcoming). Conversely, we could consider the archaeology of the "living" Internet, but even here we could not ignore the vast web or mesh of infrastructure that underpins it. For example, it has been estimated that Internet data centers consume 30 gigawatts of electricity per annum, roughly equivalent to the output of 30 nuclear power stations. Similarly, the physical devices involved, which are increasingly mobile in themselves (tablets and smart phones) incorporate a wide array of raw materials, such as rare earth metals, sapphires, or lithium, that are sourced from all parts of the world. Finally, given the obsolescence built into the technology, there are vast numbers of redundant computers and cell phones, many of which cannot be practically recycled and thus become waste (Slade 2007).

Historical Background

The Internet began with the ARPA or DARPANET, a small group of computers in military and academic sites in the USA (although its ancestors were the telegraph, telephone, and teleprinter). The Advanced Research Projects Agency, in turn, had its origins as the Eisenhower administration's reaction to the perceived threat posed by the launch of Sputnik 1 in 1957. As a parallel development, commercial computer networks soon began to appear, most notably CompuServe, founded in 1969. All of these systems depended in part on the modem, a device for dialing up an occasional inter-device connection on the telephone network, which had its origin in

teleprinter technologies of the 1920s. As these networks gradually spread across academic institutions and business, the next major step in Internet history was the rapid adoption of personal computers, marked by the appearance of the Apple Mac and IBM PC in the early 1980s. These in turn had their origins in work by Douglas Engelbart (the mouse) and Alan Kay (the GUI and local area networks; Kay 1977). Through the use of local area networks and the first dial-up connections, personal computers began to be used for communication and exchange of information through systems such as Usenet (1979) and FidoNet (1984) and other bulletin board systems that emerged in the mid to late 1980s. The first automatic modem, manufactured by Hayes, was marketed in 1982. What we now call the Internet is, effectively, the result of the gradual integration of separate government, academic, and commercial networks as each adopted the Internet protocols (TCP and IP). Thus, for example, the UK JANET was set up between British universities beginning in the 1970s, but only adopted IP in 1991.

Whilst these systems had users numbering in the tens or hundreds of thousands, it was the work of Tim Berners-Lee and Robert Cailliau, beginning in 1989, that turned the net into a global phenomenon (Reid 1997; Berners-Lee 1999). Initially intended as a document-sharing system for academic scientists, the HTML protocol was rapidly adopted for a wide variety of purposes, especially when Marc Andreessen and his colleagues at the National Center for Supercomputing Applications developed the Mosaic browser in 1993. Crucially, Andreessen incorporated the < IMG > tag into HTML, which enabled web pages to include pictures. It can be convincingly argued that from this point, pornography became one of the significant drivers behind the spread of Internet use, despite the attempts of the newly founded World Wide Web Consortium to prevent this (Berners-Lee 1999; Channel 5 2007). Other protocols for Internet data sharing lacked this graphical content. Gopher (developed by Mark P. McCahill), the only serious competitor for WWW, was hampered by the licensing requirements imposed by the University of Minnesota (Reid 1997).

Alternatives to the Internet/www *did* exist. The French Minitel system, launched by PTT in 1982, was based on simple video text terminals that were leased for free to telephone subscribers. The system provided an online phone book, mail order, and travel ticket purchasing and at its peak had over nine million subscribers. By the early 1990s, it had spawned the kind of online shopping and quasi-dot com start-ups that would only appear 10 years later on the web. Although adopted in a number of other countries, the system was only successful, outside of France, in Belgium, largely because other providers tried to charge too much for the service and/or the leasing of terminals. Only in 2012 was the Minitel service finally terminated.

The later 1990s witnessed the so-called browser wars and early attempts to commercialize the Internet, particularly following the development of SSL (Secure Sockets Layer) protocols in 1995, which enabled secure financial transactions across the Internet. For several years, Microsoft's Internet Explorer and Andreessen's Netscape attempted to dominate the web, and here it is worth noting that the business model adopted by Netscape, that of trying to build a web-based "platform" on top of the (Windows) operating system, failed at the time, but is rapidly coming to fruition (see discussion of cloud computing below). By 2001, early attempts to monetize the Internet ended in the so-called dot-com bubble, precipitated by excessive speculation and the failure of entrepreneurs to understand how the Internet could be used for business. In particular, it became apparent that the web itself, at the time, could not be a means of making money, but only as the platform upon which commerce could take place.

The subsequent decade has been marked by the emergence of several major strands of activity, in particular, online shopping, media downloads/streaming (music and film), advertising, and social networking, often dominated by those companies such as Amazon, Google, and eBay, which had survived the crash of the dot com bubble. At the same time, there have been claims for the emergence of a Web 2.0, typified by Creative Commons' activities such as

Wikipedia and, to a more limited extent, Facebook, YouTube, MySpace, Twitter, or SoundCloud (O'Reilly 2005). The growth of Internet usage, particularly in the late 1990s, had been marked by anarchic and often utopian approaches to the future of networked activity (e.g., Rheingold 1994). Whilst it is true that no entity, national or commercial, has succeeded in completely controlling Internet activity, it is certainly the case that there is a growing asymmetry between users and providers, symbolized by the fact that the dominant DSL protocol for broadband is asynchronous, i.e., that downloading and uploading are separate processes with increasingly asymmetric speeds (Kleiner & Wyrick 2006). Equally, it can be argued that users increasingly perform unpaid work in creating content that companies, such as social networking sites, exploit for profit.

Recent years have been dominated by the mobilization of the Internet, initially through laptops and PDAs, but increasingly through the use of smart phones that have Internet capabilities. Although the concept dates to the early 1970s, the first Internet-enabled phones appeared in the late 1990s, and the prevalence of such devices is probably marked by Apple's iPhone of 2007. In as much as the cell phone has largely bypassed landline-based systems in the developing countries of Africa, it seems likely that the same will become generally true of Internet usage. From an archaeological/material culture point of view, then, the Internet will have at least two ages: its wired and wireless eras, which would require quite different characterizations that might be termed, respectively, sedentary and nomadic. Here, whilst the utopians of the 1980s and 90s envisaged a virtual reality like Gibson's "consensual hallucination," the actuality is increasingly an interpenetration between the virtual and "real" in an augmented reality.

Key Issues

Software Archaeology

Although it might be thought that software programs or applications are analogous to documents, their dynamic characteristics imply a more artifact like quality (Graves-Brown 2009). Whilst they only exist as quantum states in millions of transistors, programs can print information on paper or launch nuclear missiles. The very iconography of graphical user interfaces implies an artifactuality; there are buttons and sliders and objects to be dragged or stretched. The soft Internet can be approached at several levels. We may, for example, examine the history and development of the actual code, as in the genealogy of the web browser, beginning with Berners-Lee and Cailliau's command-line browser, through Mosaic, Internet Explorer, Netscape, and Mozilla Firefox (all based on the same basic code) and other browsers such as Opera, Safari, and Google Chrome which have arisen more recently and (to some extent) independently (Graves-Brown 2009).

At another level, archaeologists can also study the various "artifacts" created on the Internet, particularly in the variety of virtual "worlds" and online games, such as Second Life or World of Warcraft (and increasingly in game environments associated with social media such as Facebook). Whilst the utopian vision of an immersive cyberspace has not entirely come to pass, virtual worlds are now used by millions of people and include objects that can be made, owned, and sold as if they were physical goods. As Harrison (2009; see also Guest 2007) has pointed out with respect to Second Life, such virtual artifacts can also come to have a history and be regarded as a form of virtual heritage. In a similar way, the role of virtual artifacts in the augmentation of reality can be studied.

What distinguishes virtual from physical artifacts is their so-called non-rivalrous nature. Every copy of an image or MP3 is identical and does not in any way detract from the "stock" of the original. This in turn leads to quite different concepts of ownership, typified by the concept of Creative Commons, since items can be freely shared by their creators at no cost to themselves. However, the concepts of copyright, license, and subscription are increasingly important areas of contestation as capitalism attempts to monetize the Internet.

Politics

The politics of the Internet revolve around access and ownership. There are still large segments of the populations of both developed and developing countries that are disenfranchised by a lack of access to the Internet. Similarly, governments are increasingly attempting to control access and traffic, as in the case of the so-called "Great Firewall of China" by which the PRC has attempted to filter its citizens' access to information. In extremis governments may simply seek to "turn off" the Internet and mobile phone networks. This is clearly becoming critical in the light of events surrounding the Arab Spring of 2011, where use of social media is said to have been crucial in mobilizing opposition to dictatorial governments. Elsewhere, so-called democratic governments have sought ways to control and or monitor Internet activity. These range from the V-chip incorporated into US televisions to filter content to the ECHELON interception system that has been implicated in both political and industrial espionage by western nations. At the end of 2012, the UK government was attempting to extend its powers to monitor Internet traffic, supposedly in order to counter terrorism. However, in contrast to this paranoia-inducing activity, it should be noted that contemporary methods of encryption (such as PGP, developed by Phil Zimmerman in 1991) are virtually impenetrable, even with the use of supercomputers.

The second aspect of the politics of the Internet that may be of interest to archaeologists concerns its exploitation by capital. At the macro level, this concerns the extremely free movement of capital facilitated by Internet communication, which through tax havens and other activities, has become implicated in the financial crisis that began in 2007–2008. At a more local level, as noted above, the ownership of virtual and physical property is increasingly crucial. At the physical level, this is characterized by attempts to control and monopolize copyrights and patents, as in the case of Google's purchase of Motorola and the numerous patent infringement suits surrounding smart phones in 2011–2012. At the virtual level, issues of ownership of content have arisen, typified by the (apparently apocryphal) controversy surrounding Bruce Willis' iPod (Willis 2012). Unlike physical books or audio recordings, the purchaser does not own the "thing," so much as a license to use it. The question then arises as to whether such items are property and whether Bruce Willis' children can inherit the content of his iPod.

At another level, the emergence of so-called cloud-based software/data storage brings us back to the Microsoft/Netscape conflict of the late 1990s. Thus, for example, the presentation application Prezi (unlike Microsoft PowerPoint) is not sold under license but as a subscription, based around the cloud sourcing of content. Unlike the earlier model, the user does not own, but must continually subscribe to the virtual artifact. Thus, in effect, cloud sourcing shifts the platform from the physical to the virtual, where a "new" method of monetizing usage can be deployed (as Netscape had originally attempted in the late 1990s). Here, it may be argued that the cloud model of networked computing is in fact a reversion to the earlier model of mainframe computers served by so-called thin terminals, i.e., devices that are little more than a keyboard/mouse and a screen.

Future Directions

The Internet can be studied by archaeologists at a number of levels. These include both its physical and virtual infrastructure and the virtual artifacts of all kinds created by and through this infrastructure. The nature of the Internet is always changing, at times in apparently cyclic patterns. Thus, the use of mobile devices and cloud computing may see a return to a model of information technology not dissimilar to that found in mainframe computers of the 1960s, 1970s, and 1980s. With the consolidation of data centers, it might not be too farfetched to foresee a time when there *are* only ten "computers" in the United States! These processes are driven by both global/national politics and the desire of capital extract profit from the Internet, countered by those who retain the utopian ideal of free "peer-to-peer" exchange of information.

Internment and Prisoners of War in Historical Archaeology

Harold Mytum
Department of Archaeology, Classics and Egyptology, University of Liverpool, Liverpool, UK

Introduction

The archaeology of prisoners of war, including both the sites of their incarceration and the artifacts they used and produced during confinement, has recently developed into a major element of historical archaeology, linked to the broader fields of conflict studies and confinement studies. While many prisoner of war camp sites retain no above-ground features, others still have some upstanding buildings. Only a few camps have thus far been excavated, but many artifacts that never entered the archaeological record are retained by private collectors and museums, often because of their craft qualities and evidence of human ingenuity in difficult circumstances. Another major source of information comes from the study of graffiti, often found on the walls of buildings in major camps, but also in other temporary prisons or buildings converted during wartime to hold prisoners of war.

Definition

Prisoners of war are military personnel or civilians who have been incarcerated without trial during a conflict between two nation states. Prior to the eighteenth century only small numbers of active military officers were captured and held to ransom, the other ranks being enslaved, massacred,

or allowed to flee. As armies and navies became larger, and the threats increased of captured forces returning to fight for the opposition following release, each nation tended to retain control of such prisoners until an exchange for its own captured forces (Mytum and Carr 2013a). However, from the Napoleonic wars onward such exchanges were less frequent, and so the concept of a military prisoner of war camp developed. In the Boer war at the end of the nineteenth century the British considered that civilians were a threat, and this was the first occasion when significant numbers of noncombatants were forcibly interned for the first time.

One of the important factors in the development of prisoner of war camps is the creation of xenophobic stereotypes of the "other" generated between nations at times of war. Whereas until the early nineteenth century officers of all sides could be expected to behave in an honorable way and not attempt escape from parole in the community, as mass media and more technologically advanced methods of warfare altered the attitudes to conflict it became necessary to isolate the captive aliens to prevent escape, sabotage, espionage, and unrest among the native population.

Prisoner of war camps should not be confused with concentration camps, where extermination of the inmates either by execution or forced labor was the purpose, or with any forms of detention during a civil war or totalitarian regime where individuals of the same nation were being held, though some sites are hard to place as either prisons or camps. For example, the sites of incarceration of the Mau Mau in Kenya, Republicans in Ireland, or Guantanamo Bay in Cuba would be seen as prisons for criminals by one side and camps for captured combatants on the other, and their assignment indicates the political relevance that this type of research entails (Myers and Moshenska 2011). These are all alid topics within confinement archaeology (Casella 2007) and can be grouped along with examination of asylums, workhouses, prisons, and other institutions designed to control marginalized groups in society. While prisoner of war archaeology may be placed within the field of conflict archaeology, because internment only took place because of war, in many respects the types of physical control and managerial structures, as well as inmate experiences, more often mirror those found in other institutions that facilitated confinement (Beisaw and Gibb 2009). The harshest prisoner of war camps were only marginally better than concentration camps, and the most tolerant, especially when for civilians, resembled relatively benign institutions albeit surrounded by barbed wire (Fig. 1). Some camps were created out of existing buildings, especially in the eighteenth century when castles and military establishments were converted, but from the Napoleonic period onward temporary sites were increasingly

Internment and Prisoners of War in Historical Archaeology, Fig. 1 Photograph of World War I civilian German internees at Douglas Camp, Isle of Man. (Photograph courtesy of Manx National Heritage)

popular. Early efforts at managing the prisoner of war numbers involved the use of hulks – old ships without their masts – but these were unhealthy and difficult to manage. The Napoleonic prisoner of war camp at Norman Cross, near Peterborough, England, sets a new standard of organization and control (Mytum and Hall 2013), subsequently copied or independently invented elsewhere. Most prisoner of war camps were constructed with limited life spans in mind, and while the majority have since been erased from the landscape, a surprising number of structures still stand, often being reused for agricultural or industrial purposes. The artifacts produced by prisoners with their large amounts of spare time survive in remarkable numbers as they were both sold outside the camps as a form of income generation or retained by prisoners as keepsakes on release.

Historical Background

Research into prisoners of war was initially an interest of historians, with the first studies in the early twentieth century (Abell 1914) in the UK and USA (Hesseltine 1930). Until the later twentieth century, archaeologists only noted prisoner of war phases as part of a site sequence, as at Portchester Castle (Cunliffe and Garratt 1995), but at this point those researching aspects of the American Civil War began to include the prisoner perspective alongside that revealed at battlefields and barracks. Significant programs commenced in the 1990s at Camp Ford, Texas (Thoms 2004), and Johnson's Island, Ohio (Bush 2000), with other fieldwork linked to public interpretation at the most infamous camp of Andersonville and at Fort Pulaski, both in Georgia (Jameson 2013). Research also began at about the same time on later prisoner of war camps, notably World War II Camp Hearne, Texas (Waters et al. 2004), and at the Japanese American camps including Manzanar (Burton et al. 1999). Parallel with the archaeological work, the artifacts made in the camps were studied from an anthropological perspective (Dusselier 2008). The impact of the Boer War has been researched from many different viewpoints, and this has included archaeological work on both African and Afrikaans internment (Dreyer 2001).

Archaeological research on prisoner of war sites and material in the UK and Europe only began in the twenty-first century, although it is now being actively pursued in many countries (Myers and Moshenska 2011; Mytum and Carr 2013b). One strand has been from academics and museum curators from a wide range of disciples interested in the creativity of prisoners (Carr and Mytum 2012) and the links between these products and others – Trench Art – made by soldiers during wartime (Saunders 2003). There has also been increasing interest from heritage managers who are now recognizing camps as valuable and significant archaeological sites. They are seen as important in terms of national and regional memory yet are fragile parts of the landscape because they were made for short-term use. Thus far, only a few prisoner of war camps are protected by any legislation, but there have even been excavations of such sites in advance of development (Early 2013). In Australia, there has been some survey to assist in the development of management strategies, but as yet no significant further research. Important camps survive, however, from both the First and Second World Wars, and in some cases museums hold important artifact collections associated with these sites and their inmates.

Key Issues/Current Debates

Many of the ethical and interpretive issues are similar to those within the wider field of conflict archaeology, but often prisoners of war were aliens in closer contact with home noncombatants than was normally the case in wartime, and this creates additional issues of memory, guilt, blame, and forgetting (Burström 2009). Often prisoner of war archaeology is part of a painful heritage that makes it both significant and dangerous.

Prisoner of war archaeology often reveals guilt, not only of the losers in war but also of victors whose treatment of those in their care was often inappropriate. The materiality of

Japanese American camps for interned civilians, and their study by academics and the US National Park Service, has given literally concrete evidence and reminders to reinforce the claims of survivors and their descendants (Burton et al. 1999; Dusselier 2008; Mytum and Carr 2013b). While responsibility for the forced labor camps for prisoners of many nationalities established across Europe by the Nazis can be separated from those alive today, there is a hidden legacy that research reveals. The work of these prisoners was often to the benefit of local residents, with improved infrastructure and profitable contracts for local firms. Archaeological survey and excavation can reveal injustices and oppressions buried beneath a generation or more of forgetting (Burström 2009). The complexities of the past are revealed, with the simplistic nationalistic narratives of allies and enemies, of stoical home front and heroic warriors, challenged and undermined. The extent to which this past is usefully unearthed, and what is then to be done with it, provides archaeologists in academia and in heritage management with dilemmas that are not always easy to resolve; this is evident in much current research (Myers and Moshenska 2011; Mytum and Carr 2013b).

The confinement in camps was primarily a physical, embodied experience, and under these extremes some of the cultural perceptions of the body, privacy, and self-worth are both revealed and challenged. How this was managed and coped with, again often using the material world of the camp and the impoverished range of objects within it, gives archaeologists great opportunities to study underlying attitudes that lie buried within more normal situations. The agency of those imprisoned can be compared and contrasted with that of the captors, and both had to formulate new structures of authority and management for these abnormal conditions. Moreover, most camps were single-sex institutions, and so many social structures, values, and behaviors had to be reworked in these partially domestic situations. Just as national identity was highlighted in war, so gender roles had to be renegotiated within the camps, a theme in a number of recent studies (Carr and Mytum 2012; Mytum and Carr 2013a).

Internment and Prisoners of War in Historical Archaeology, Fig. 2 Cigarette case made from a mess tin by a World War II Italian prisoner of war (Author's photograph)

Identity is a major theme linked to prisoner of war archaeology and other cultural studies in this interdisciplinary field (Carr and Mytum 2012). Internees were in that situation because of their own or other's perception of their identity as aliens within conflict. This is often then revealed in the material culture produced and used within the camps, as their occupants struggle to come to terms with their situation, and placement within what during wartime at least was an antagonistic milieu. Despite close observation and controls over access to resources, many acts of resistance can be identified from the most obvious such as escape tunnels, to more subtle indicators of national identity through use of symbols and language (Carr and Mytum 2012; Mytum and Carr 2013b). Many items of material culture survive as memory works from the camps and are in the possession of local museums or descendants of the internees (Fig. 2). Excavated evidence, however, or graffiti on structures still standing can also reveal the same processes.

International Perspectives

All archaeological studies have an element grounded in local situations, but as products of international conflict, prisoner of war archaeology always has an international dimension. However, what is drawn from the evidence of prisoners and their camps varies greatly with context. The issues

can be considered from an international perspective in terms of particular global conflicts – how civilian or military personnel were interned in many different countries, from the Boer War onward (Mytum and Carr 2013b). Some conflicts that were internal – such as the American Civil War – also reveal how the creation of the "other" was a product as well as a cause of war and could lead to a cycle of increasingly inhuman treatment of enemy captives (Hesseltine 1930). In contrast, for many conflicts there was considerable effort to make the camps meet international humanitarian standards, often because of the nation's fear of reprisals against its own capture held in the enemy's camps. The comparative study of site organization, management of security, hygiene, food, and clothing reveals remarkable similarity across both time and space. How far this was through learned experience and how far it was based on managerial deductions in independently assessed cases is still unclear.

Heritage bodies in all parts of the globe have been slow to recognize the cultural significance of prisoner of war camps from past conflicts, but this is now rapidly changing. While the USA has taken the lead in both researching, protecting, and presenting parts of this heritage (Burton et al. 1999; Jameson 2013), many state heritage organizations in Europe and Australasia are now identifying sites, creating policies, and implementing albeit often limited plans for protection and management.

Future Directions

The interdisciplinary nature of prisoner of war research is still in its infancy, and there is great potential for scholars, heritage managers, and field practitioners to work together on the wide range of sources that survive for this subject. Only recently have scholars working independently in their own disciplines realized that parallel and complementary research is taking place by others (Carr and Mytum 2012). Prisoner of war archaeology can provide an important contribution to this evolving interdisciplinary dialogue, not only because of the technical skills inherent to the discipline but also because of experience in working with descendant communities, communicating with the public, and awareness of the difficulties as well as opportunities that revealing the past can bring.

Interdisciplinary collaboration also brings prisoner of war archaeology to the fore in a range of topics where previously archaeologists may have been marginal. Camps, as tourist attractions or parts of a landscape to be preserved, lie within the spectrum of what is termed dark tourism, and a few are now preserved as visitor attractions (Fig. 3). The same site can have many different meanings and values to a range of visitors, from a place of personal or family suffering, to a symbol of victory over the enemy, to evidence of a past conflict with which the observer has no strong attachment. Archaeologists are only beginning to consider these issues, though some American

Internment and Prisoners of War in Historical Archaeology, Fig. 3 Eden Camp Modern History Museum, North Yorkshire, England, originally constructed to house World War II Italian, German, and East European prisoners of war (Author's photograph)

Civil War sites are the most advanced at the moment in this regard (Jameson 2013).

Fieldwork, and particularly excavation, has been limited to date, yet relatively restricted work on a variety of Japanese American camps in the USA (Mytum and Carr 2013b) reveals both the site-specific and wider comparative value of such investment. From trial work on the UK Napoleonic site of Norman Cross (Mytum and Hall 2013) to the extensive developer-led excavations at La Glacerie World War II camp in Normandy, France (Early 2013), it is evident that further excavation on UK and European sites would be highly rewarding. The combination of excavation data, surviving curated material culture, official and personal documents, and oral testimonies can create a rich source which is only just being appreciated and studied.

Interpretation (Including Historic Reenactments): Current Approaches

Charles R. Ewen
Department of Anthropology, East Carolina University, Greenville, NC, USA

Archaeologists don't usually enter the profession because they are anxious to work with living people. They have a passionate interest in the past, and its relevance to the public is a secondary concern for most. Interpreting what they have dug up is generally shared with colleagues through professional journal articles or conference presentations. However, most archaeologists realize that, since they are footing the bill, the public is entitled to know about what they have found out. So, once these interpretations have been made, how does the public find out about them? Traditionally, the public could find out from the horse's mouth by visiting archaeological digs and speaking to the archaeologists. However, opportunities for this type of interaction are limited, and the archaeologists often resent the intrusion into their digging time. The interaction in the field is usually better when archaeologists work with professionals who are trained to deal with the general public. However, few digs can afford full-time tour guides. However, technology has been employed to mediate the public experience with the archaeologist. Today the ways that the majority of the public typically learns about archaeological interpretations are through television programs, museum exhibits and living history reenactments, and social media.

Some archaeologists have embraced the site visitor as an opportunity to get their perspective heard. The field schools of the University of Massachusetts have opted for a somewhat unusual approach to archaeological interpretation to the public. They have employed critical theory to examine ideologies of the past that have resulted in social inequality in Annapolis (Potter 1994). They then attempt to show how our perceptions of the past influence our actions in the present. Their website (Archaeology in Annapolis n.d.) encourages feedback from the tours. The results suggest that the public was engaged when the relevance of the archaeology was made explicit.

Williamsburg is a more conventional public interpretation that is built on archaeology, literally. There, every historic building rests on an archaeological site. The discoveries of the archaeologist are witnessed by visitors and directly interpreted on the reconstructed site in the form of architecture, artifacts used at the structure, and the characters portraying the site's residents. It's a popular and effective way of communicating the past to the present, and one gets a sense of what eighteenth-century living was like (if they had OSHA standards and modern sanitation codes).

Down the road from Williamsburg is a site that combines elements of museum interpretation with living history and adds interactive web resources into the mix. The Jamestown Rediscovery project (Jamestown Rediscovery n.d.) boasts ongoing digs, an Archaearium (a museum specifically tied to the archaeology), and proximity to a more traditional museum and living history recreation of Jamestown and a Native American village. The elements all intermesh to provide the public with an immersive historical archaeological experience.

Across the pond, the Jorvik Viking Centre in York, England (Jorvik Viking Centre n.d.), presents a less sanitized version of the past by taking visitors through a recreated Viking settlement in a moving cart. The visitors see animatronic (and aromatic!) Vikings going about their business and experience the sounds and smells of their daily life. The Disneyesque ride ends with a tour through a gallery of artifacts recovered from the site. Throughout the visit, there are narratives explaining the connection between the archaeology and the interpretation. It's an immersive experience that is popular with the public, though some archaeologists are wary of the showmanship.

Not all archaeologists are onboard with living history interpretations of their work. Some feel this presents a skewed vision of the past based on the present and smacks of edutainment. Whatever the bias, the public clearly enjoys this type of interpretation. And if the purpose of the archaeological interpretation is to inform the public, they have to be listening first.

This leads us to, perhaps, the most controversial and most pervasive way of interpreting archaeological sites: television. Public television has been running archaeological documentaries for many years. But it was Britain that first really popularized archaeological interpretation for a general audience with their half-hour series Time Team. The premise for the show was that the Time Team cast would visit an ongoing archaeological project bringing an array of remote sensing and computer equipment. In 3 days they would have solved one of the questions that had been vexing the lead archaeologist before moving on to their next project (Hilts 2012). The show lasted an impressive 20 seasons and even had a spin-off in the USA with Time Team: America.

If not enthusiastically endorsing Time Team, archaeologists tolerated the popular excursion into their domain. Such was not the case with two later cable network programs, Spike's "American Diggers" and National Geographic Channel's (NGC) "Diggers." Both shows portrayed metal detectorists looking for artifacts and then presumably selling them. Both evoked protests from the professional archaeological community, but only the NGC responded. In a rare demonstration of cooperation, the NGC worked with archaeologists to remove the offensive aspects of the program and even hired an archaeologist to work with the detectorists on-screen. Again, the show was never fully embraced by archaeologists, but the protests stopped (Ewen 2014).

Like historic reenactments, televised archaeological programs and cinematic portrayals of archaeologists will always be viewed with caution by the profession. Walking the line between entertaining the public and educating them is a tightrope act. However, with archaeological interpretations of all kinds more available than ever through blogs, video clips, and social media, the archaeologist must promote their work publically or cede the field to the pseudoscientists.

Interpretation in Archaeological Theory

Gavin Lucas
University of Iceland, Reykjavík, Iceland

Introduction

The concept of interpretation in archaeology can be understood in many different ways. At one level, it is a general term used to describe the

construction of archaeological knowledge about the past from evidence surviving in the present; as such, many archaeologists use the term interchangeably with others, including explanation where no defined qualities are ascribed to either. However, the term "interpretation" also carries more specific connotations which distinguish it from explanation, premised on a different perception of what counts as knowledge. This distinction can be traced back to the nineteenth century and a separation in German scholarship made between the natural and human sciences as involving two different methods and types of knowledge. Archaeology has always occupied an uneasy position in this separation, and although on the whole its roots lie within the humanist tradition, archaeological interpretation rarely explicitly contrasted itself against explanation until the 1980s with the emergence of postprocessualism. This was largely as a reaction to the equally explicit development of the concept of explanation under New Archaeology and processualism in the 1960s and 1970s. As the battle between processualism and postprocessualism has faded out and more accommodating yet diverse theoretical positions have become the norm, it is questionable how far the distinction between explanation and interpretation remains a viable one.

Definition

The concept of interpretation, understood in its specific sense as a mode of knowledge production within the humanities, emerged under a philosophical stream called hermeneutics, which was initially a reflection about the interpretation of meaning in ancient texts. In traditional European scholarship, it was thus closely linked to three different concerns: philology, biblical exegesis, and the law (Bleicher 1980). In the nineteenth century, however, hermeneutics developed into a more general philosophical method in Germany, especially through the pivotal influence of Friedrich Schleiermacher. In Kantian fashion, Schleiermacher attempted to systematize hermeneutics by defining the possibility and limits of textual interpretation; at the basis of his approach was the importance of highlighting the reciprocal relationship between authorial intention and the wider linguistic context. That is, to understand a particular word or phrase in any given text, one needed to relate the author's ideas as expressed in that particular instance, with other parts of the text and even the language as a whole.

Although pivotal, Schleiermacher was only the prelude to the more important figure of Wilhelm Dilthey who used hermeneutics to provide a theoretical foundation to the humanities as a whole and in doing so underlined a distinction between the natural and human sciences. Dilthey took the Kantian model to its ultimate conclusion in his unrealized project of a *Critique of Historical Reason*, which replaced the transcendental (i.e., universal) categories of Kant's pure reason with the psychological and historical context of particular individuals. In short, human understanding and knowledge is always mediated by its particular personal and social context. At the core of Dilthey's philosophy lies the concept of interpretation (*verstehen*) as the methodology of the human sciences (*Geisteswissenschaften*). Dilthey characterized interpretation as a form of knowledge which emerges from a first-person perspective on the world – that is, the world as seen from a human being's point of view as they are immersed in the world. For Dilthey (and others before him like Giambattista Vico and Alexander von Humboldt), such a first-person perspective underlined the fact that we can understand other people because we are one of them. It gives us an insider perspective. He contrasted this with explanation (*erklären*) which adopted a third-person perspective, as exemplified in the natural sciences (*Naturwissenschaften*). Here, one understands trees or rocks in a different way; because we are not trees or rocks, we can only ever understand them from an external or outsider's point of view.

To illustrate this, consider a person standing by the side of the road hailing a taxi. One way to understand this situation is in terms of cause and effect between external objects – the raised arm, the directed gaze of the person, and the shape, color, and markings of the vehicle that stops. This would be an example of explanation. For Dilthey this was a very limiting way to understand

what is happening; in contrast, we can see this event from the point of view of the person by the roadside or sitting in the taxi. In this context, the raised arm needs to be understood not as a cause but as an intention (e.g., "Taxi, stop!") and the taxi stopping understood as the taxi driver reading that intention. The cause and effect approach only really offers us a *correlation* between two events – the raised arm and a vehicle of a certain type stopping; to fully understand that correlation, we need to grasp the intentions and meanings inscribed into these events, and this requires adopting an internal or first-person perspective on the event. This is what is also meant by empathetic understanding – not some kind of subjective or psychological projection of myself onto another, but simply to recognize the meaningfully constituted context of those events in the world which involve human beings.

Although Dilthey developed the concept of interpretation in this way in the nineteenth century, it was popularized by the sociologist Max Weber in the early twentieth century and used to promote an interpretive sociology which was to contest the French positivist sociology of Comte and Durkheim. The French sociological tradition, unlike the German, adopted a much less divided view on the relation between the natural and social sciences, seeing them more as sharing a similar methodology and philosophy. However, the German hermeneutic tradition, especially after Weber, impacted the way sociologists and anthropologists saw their disciplines, and by the middle of twentieth century, many scholars within the social sciences in the Anglophone tradition increasingly reflected on the special character of their methods and forms of knowledge. One of the earliest studies was Peter Winch's investigation into the nature of social science, linking Weber to Wittgenstein and which had a massive impact on subsequent social theory (Winch 1958). It provided the philosophical foundations to the interpretive turn in many of the social sciences such as anthropology represented in the work of Clifford Geertz from the 1970s and archaeology through Ian Hodder from the 1980s.

Concurrent with this interpretive turn was the emergence of a new wave of philosophical work in hermeneutics associated with writers like Emilio Betti, Karl-Otto Apel, Hans-Georg Gadamer, Jürgen Habermas, and Paul Ricoeur, many of whose ideas were taken up within the social sciences, including archaeology. Gadamer in particular is discussed further below, but the key development marked by his work among this group is the extension of interpretation away from being simply a methodology of the human sciences toward a way of defining human existence. If Dilthey expanded Schleiermacher's concept of interpretation from being about texts to defining a method for all human sciences, Gadamer took it one step further and generalized the concept as a definition of human understanding and, indeed, human being. In this, Gadamer was heavily influenced by (and was a student of) Heidegger; just as Dilthey's concept of *verstehen* had influenced Husserl (the founder of phenomenology), Heidegger's phenomenology later transformed this original concept into something much broader. It is thus important to note the close historical connections between the hermeneutic and phenomenological traditions, a connection which one also sees developed in archaeology through the work of Bjørnar Olsen, Christopher Tilley, and Julian Thomas. On that note, let us now turn to the more particular historical background of how the concept of interpretation has been used within archaeology.

Historical Background

Archaeologists rarely if ever explicitly referenced the hermeneutic tradition discussed in the last section – not until the advent of postprocessualism and the reaction to the logical positivist models of archaeological knowledge espoused by the New Archaeologists. However, this is not to say that archaeologists working in the early and mid-twentieth century did not share many of the same assumptions connected to this tradition; indeed the term interpretation was widely used and was probably the most common term for the process of archaeological reasoning. The Egyptologist Flinders Petrie, for example, explicitly paralleled archaeological interpretation with the

legal process, as did the historian and archaeologist R. G. Collingwood. Such perspectives on archaeological interpretation show a clear link with the humanist tradition and textual interpretation, especially in the case of Collingwood who developed his own particular brand of historical interpretation modeled on the hermeneutic concept of *verstehen*. However, archaeology always occupied an uneasy position within academic disciplines, straddling a widely held division between the natural and social sciences. Commonly perceived as a very young discipline (especially compared to history), its status remained ambiguous; at the same time, for some like Petrie, it was precisely because of this that archaeology could counter the increasing tendency toward what C. P. Snow was later to call the two cultures (Petrie 1904: viii).

There was, however, another dimension to this ambiguity. This was in the recognition that archaeology is not a completely unified discipline, but rather exhibited a major fracture between prehistoric and (proto-) historical archaeologies, the former lying closer to the natural sciences and the latter to the humanities. Historically this is well attested as the emergence of prehistoric archaeology in the mid-nineteenth century was closely aligned with natural scientists like geologists as against the humanist background of those working in classical and medieval archaeology. This schism was addressed in depth by the British archaeologist Christopher Hawkes in the mid-twentieth century (Hawkes 1954). Drawing a distinction between text-free and text-aided archaeology, he defined different modes of archaeological cognition or interpretation depending on whether textual sources existed alongside archaeological ones (parahistoric/telehistoric) or not (antehistoric). For Hawkes these represented very different types of interpretation, one historical and the other "processual," and he linked them to his famous ladder of inference. Ultimately of course, even though he was a prehistorian, Hawkes saw historical interpretation as the richer one because it dealt with what was more *human* in human societies.

Hawkes' views were widely shared by many of his contemporaries, especially in Europe, who, while recognizing the importance of natural sciences to archaeology, preferred to see their discipline as part of the humanities, not the natural sciences. Jacquetta Hawkes vociferously argued that the ultimate goal of archaeology was historical reconstruction and that while the natural sciences formed a part of archaeology, their role was largely methodological, not theoretical. Her views were stimulated as a response to the growing influence of New Archaeology within Britain and the opposite stance which it represented: the subsumption of historical interpretation to styles of explanation modeled on the natural sciences. In Britain, this shift is more abrupt, but in North America one can see the transformation taking place more gradually during the preceding decades. For example, archaeologists like John Bennett and Walter Taylor in the 1940s explicitly defined interpretation as the ascription of functional or historical meanings to archaeological data, which Taylor considered as a penultimate stage in the processing of archaeological data, prior to more generalizing steps such as the construction of chronologies, culture historical syntheses, or cross-cultural comparative generalization (Taylor 1983). Indeed, sometimes one can see the interpretative stage as an incipient version of middle range theory, pertaining to the understanding of the archaeological record in terms of the particular events which created it as opposed to more generalized syntheses. This is reinforced by Ascher's later discussion of analogy which aligns analogy with the interpretive stage of archaeological work, after data collection but prior to synthesis.

Thus, what for Hawkes and many archaeologists, both in Europe and North America, was the ultimate goal of archaeology – historical reconstruction – was for a growing number of North American archaeologists only a middle stage toward a grander goal of scientific explanation, conceived as cross-cultural generalization. This shift was however gradual, and as a result, the concept of interpretation became increasingly ambiguous in North America. Thus, while some authors used the term interpretation to cover *all* aspects of archaeological reasoning, from typologies to historical reconstruction, Willey and

Philips used the term processual interpretation as the particular *archaeological* form of scientific explanation (1958). In Britain, the leading exponent of New Archaeology David Clarke similarly used the term *interpretive theory* to refer to a natural science model of explanation which capped a whole series of lower-level theories relating to archaeological reasoning (Clarke 1973: 17). It is only with Binford and the New Archaeology in the 1960s that interpretation seems to almost disappear from North American archaeological vocabulary to be replaced by explanation, a shift that is very emphatic in Binford's seminal paper "Archaeology as Anthropology" (1962). This of course is linked to the adoption of logical positivism and the desire to model archaeological knowledge after philosophies of the natural sciences.

Britain, alongside Scandinavia, was somewhat exceptional in Europe in terms of its reception of the ideas of New Archaeology. While such theoretical changes from the other side of the Atlantic were noted, they were nowhere near as influential as in Britain, no doubt in part due to a shared linguistic and cultural heritage. As a consequence, archaeology and archaeological interpretation remained closely connected to history, most clearly exemplified in the German tradition which from the 1950s developed concepts and methods of source criticism and which still forms the dominant disciplinary matrix today. However, it was precisely because of the stronger reception of New Archaeology in Britain and the denigration of historical interpretation that when postprocessualism emerged in the 1980s, the concept of interpretation was not only revived but given extended and explicit discussion in a manner that it had never received before. This is especially striking in contrast to Germany, for example, where much greater theoretical emphasis focused on control of data quality through source criticism than interpretation per se, a legacy of the entanglement of Nazism and archaeological interpretation from the 1930s.

The earliest postprocessual writings which engaged with the concept of interpretation varied in the attention they gave to it. With Hodder, for example, usage was initially fairly vague, largely because he drew his main inspiration from the work of Collingwood and his method of empathetic understanding, which Hodder felt had been misunderstood (Hodder 1986: 94). For Hodder, Collingwood was simply underlining the importance of acknowledging the *meaning* content of events or material culture in the past. Although Hodder uses the term interpretation, it is by no means a frequent use – it does not even occur in the index to the first edition of his key theoretical text *Reading the Past* (1986), unlike the second and third editions. In contrast, Shanks and Tilley devoted a chapter on hermeneutics and interpretation in their *Re-Constructing Archaeology* (1987), where they affirm their role as an alternative to positivism and explanation. They argue that interpretation moves in a circular or spiral fashion in that archaeologists always bring certain assumptions or analogies from other contexts into their understanding of archaeological data, and it is through a dialectical interplay between data and preconceptions about that data that interpretation develops and moves forward (Shanks and Tilley 1987: 104–105). Drawing on the work of Gadamer, they emphasized the interpretive basis to human experience, anticipating later articulations by Olsen and Thomas (see below).

Apart from this brief but important discussion by Shanks and Tilley, the concept of interpretation within the early postprocessualism of the 1980s remained very much underdeveloped. As a response to this, the Norwegian archaeologist Bjørnar Olsen with Harald Johnsen published an important paper addressing the gap, specifically focusing on Hodder's contextual archaeology in relation to hermeneutics (Johnsen and Olsen 1992). They highlighted many of the parallels between Hodder's theory and hermeneutics, especially the emphasis on an "inner" understanding of material culture, but they also criticized what they saw as an outdated conception of meaning and pointed out inconsistencies and contradictions within Hodder's writings. In ending, they argued for the need to engage with more recent and theoretically sophisticated hermeneutic writings, singling out Gadamer as the key figure. They argued that archaeology needs to appreciate better the dialectical relation between past and present,

that our study of the past should act back on our perception of ourselves, and that modern hermeneutic philosophy can provide a stronger basis for understanding the production of archaeological knowledge. Their paper was published at one of those ironic moments, for after it had been written but before it was published, Hodder, as if anticipating this critique, published a paper in the same journal addressing exactly these concerns (Hodder 1991). In a postscript, Johnsen and Olsen acknowledge this, and while unable to comment at length, they do question Hodder's characterization of hermeneutics as a method as opposed to a philosophical theory about human existence. This is as aspect taken up later by Julian Thomas (see below).

Hodder's paper "Interpretive Archaeology and Its Role" engaged with the hermeneutic tradition in a more direct and explicit manner than his previous texts (Hodder 1991). In part this was driven by Hodder's need to distance himself and his brand of postprocessualism from the excesses of post-structuralist archaeology which many critics from within the processual core were lambasting as a descent into pure relativism, crippling archaeology from making any kind of authoritative statements about the past. For Hodder, the recent hermeneutic philosophy from Betti, Gadamer, Habermas, and Ricoeur provided a way to counter these criticisms, avoiding, as he saw it, the excesses of both positivism and post-structuralism. Archaeological data thus provided a *guarded objectivity* insofar as they represent a reality partially independent of our interpretation and can resist as much as agree with such interpretations. At the same time, our interpretation of such data is not guided by external methods of validation but needs to adhere to a principle of *internal* coherence between any particular part and the whole – which includes seeing archaeological remains as the product of human intentionality and agency. Additionally though, interpretation should also be *reflexive* and *critical* of the wider set of background assumptions and traditions within which archaeologists make their interpretations. These three facets of interpretive archaeology – objectivity, coherence, and reflexivity – combined to make a powerful alternative to the processual concept of explanation.

During the 1990s, Hodder's contextual archaeology thus morphed into an interpretive archaeology; indeed one might talk more generally of an *interpretive turn* within postprocessualism during the last decade of the twentieth century. Two volumes appeared making explicit reference to this development: one called *Interpreting Archaeology* (Hodder et al. 1995) and the other called *Interpretative Archaeology* (Tilley 1993). Shanks and Hodder suggested that the label interpretive archaeologies supersede postprocessual archaeology as a way of avoiding polarization in debate. The concept of interpretation was elaborated further in both volumes, in both similar and different ways. Ironically though, neither volume gave much explicit attention to hermeneutics but rather remained closer to a mix of post-structuralist and Marxist theory.

In the later volume, Shanks and Hodder defined interpretation as the understanding of meaning; this process of understanding, they emphasized, is a dialogue in which both sides (the archaeological record and the archaeologist) are active. As a process, it is also always ongoing; it never reaches a conclusion or closure. Indeed, even those statements which appear factual or uncontroversial are still interpretations; only the interpretive aspect has been black boxed. This in itself is necessary to enable interpretation to move forward, but at the same time such statements are potentially open to revision, like any other interpretation. In the earlier volume, however, Tilley took quite a different view. Tilley gave a broad definition of interpretation as an activity undertaken only in situations where we are unsure, where something is not immediately obvious. If one sees a figurine of a frog, one does not *interpret* it as a frog – it is just perceived directly as a frog. If the figurine exhibits an ambiguous form on the other hand, we might say it looks like a frog to me, and in that case, we are interpreting the object. For Tilley, this is why interpretation always remains open to change, lacking finality, and its "truth" remains dependent on agreement between people rather than on the evidence – in other words, the figurine is a frog if we *all* interpret it as a frog.

Tilley's volume occupies an important moment within postprocessual archaeology, subtly

marking the transition from post-structuralism to phenomenology as a guiding philosophy for its two leading contributors, Tilley himself and Julian Thomas. In many ways, it also marks the end of explicit discussion on interpretation within postprocessual archaeology; though short-lived, the series of papers and volumes mentioned here from the first half the 1990s effectively comprise most of what has been written on interpretation in archaeology in relation to the hermeneutic tradition. The fact that little has been written since is perhaps largely due to the fact that epistemic issues in archaeological theory in general have greatly diminished in importance, at least for those working out of the postprocessual tradition. Concerns have rather shifted more toward questions of ontology (Olsen 2010), reflected not only in the emergence of phenomenology from the mid-1990s within postprocessualism but also in the ontological twist given to the hermeneutic concept of interpretation, as alluded to by Johnsen and Olsen (1992) and later developed by Thomas (2004a; see below).

Key Issues/Current Debates

As suggested at the end of the last section, the concept of interpretation has more or less ceased to generate any new theoretical reflection since the mid-1990s, so there are no real current debates to speak of. Nonetheless, in this section, I will elaborate on two key issues which relate to the concept of interpretation and have engendered divided opinion: the hermeneutic circle and the double hermeneutic. The first has been more central to archaeological discussion, while the latter has only received very brief attention. In the first, I will explore the tension between those who view the circle as a method and those who see it in ontological terms, defining something central about human beings and understanding. In the second, I explore the assumption that would separate the human/social sciences from the natural sciences based on a conception of reality that is divided, between a human-centered, inner world of meaning and a material, outer world of objects.

The Hermeneutic Circle

The concept of the hermeneutic circle extends back to the origins of hermeneutic theory with Schleiermacher and Dilthey, who conceived it on the lines of a part-whole relation, chiefly in relation to textual interpretation. Parts can be anything from words to text sections, while wholes can be anything from sentences to a language. The circle describes the necessary working back and forth between the two so that an accurate understanding of meaning can be achieved. Thus, to understand an unusual word in an ancient text may require not only assessing it in the context of its sentence but also how the word is used in other sentences and how this usage might differ between different authors, literary traditions, and even time periods. It is an ever-widening circle but one that is also always a back and forth between part and whole. Expressed this way, it describes a method of interpretation, and it was this part-whole relation that Hodder adopted in his uptake of hermeneutics and which he illustrated so clearly in his interpretation of a Neolithic enclosure (Hodder 1999: 32–40). In this case study, he narrates how his interpretation of the excavation changed over seasons as it shifted back and forth between the evidence and his expectations based on prior knowledge of such sites. He describes this process not as a circle but a spiral, to emphasize that the interpretive process is always forward moving, not locked as in a closed loop, a point also made earlier by Shanks and Tilley (1987: 104). In a sense, this captures the same idea as the notion of a widening circle mentioned above. At the same time, however, in the process it is not only the interpretation of the site that has changed but also the general background knowledge about such sites and perhaps the Neolithic in general. This is why Hodder (and others) often also describes the process as a *dialectic*, because in moving back and forth between part and whole, *both* are transformed in the process.

However, one of the points made by Johnsen and Olsen in their review of hermeneutics and Hodder's version of it is that interpretation is not simply an epistemological concept about the method of knowledge acquisition, but it is an ontological concept defining something fundamental about human beings. This was taken

from Gadamer's philosophical hermeneutics which blended Heidegger's phenomenology with the hermeneutic tradition. For Gadamer, Heidegger marks a turning point in the theory of interpretation, transforming the hermeneutic circle from a methodological concept to a metaphysical or ontological one. In *Being and Time*, Heidegger described the process of interpretation in terms of the relation between fore-understanding and understanding, where fore-understanding represents our implicit way of seeing the world inherited from the particular historical tradition we were raised in. In one sense, Heidegger *temporalized* the hermeneutic circle – instead of being about the part-whole relation of words to texts, it became a past/future-present, temporal relation between fore-understanding/expectation and interpretation. Gadamer adopted this stance in his key work *Truth and Method*, using the term prejudice for this fore-understanding.

Julian Thomas developed this ontological view of the hermeneutic circle, citing Gadamer who characterizes humans as *interpreting beings* (Thomas 2004a: 24). For Thomas, interpretation is thus something we are always doing and it applies to all experience; thus in Tilley's example cited earlier, when we unhesitatingly see the figurine as a frog, this is just as much an interpretation as when we consciously decide it is a frog. All acts of experience are enframed within a pre-understanding – we always see things *as* something, there can be no raw, unprocessed or uninterpreted experience. Even if we are uncertain it is a frog, we at least see it *as* a figurine. For Thomas, this aspect of human existence, what Heidegger called the as-structure, contradicts Hodder's notion of even a partial or guarded objectivity. Quoting Gadamer, Thomas argues that interpretation is a circle we cannot escape; however, it is not necessarily a vicious circle. While implicit pre-understanding always informs any experience, any explicit act of interpretation can also alter that pre-understanding and thus alter our experience of the world. This is a basic issue of contention with the hermeneutic circle; some see it as a vicious circle, allowing no grounding in any stable or solid point; it is another version of the post-structuralist play of endless difference. However, the position taken by Gadamer and Thomas is that the circle actually *enables* understanding or interpretation in the first place.

The Double Hermeneutic

The concept of the double hermeneutic was coined by the sociologist Anthony Giddens as a way to characterize a particular consequence of interpretation in the social sciences as distinct from those in the natural sciences. The notion of a double hermeneutic captures the idea that while social scientists interpret a particular society, those interpretations can be taken up by the society being interpreted and thus constitute a second or doubled interpretation (Giddens 1984: 284). For example, a hypothetical tribal society will have its own interpretation of a certain ritual it performs, which constitute what might be called a first-order interpretation (e.g., sacrifice to the gods for a fertile harvest). The anthropologist studying them, however, will typically create a second-order interpretation to explain this ritual (e.g., releasing social tension); without this second-order description, it would hardly be anthropology. The same applies to any social science, including archaeology, where material culture patterning associated with a ritual incorporates aspects of how people in the past interpreted the ritual themselves. The doubling occurs however when these second-order interpretations are incorporated by the people being studied so that they become first-order interpretations. For example, early anthropological accounts of societies may be taken up by later descendents and integrated into their own sense of tribal identity.

Giddens' articulation of the double hermeneutic makes explicit the dialectical interplay between two frames of meaning – the sociologist and the people being studied, and how translation and interpretation from one to the other runs in both directions. When Giddens originally articulated this, it was contrasted with the natural sciences where, he argued, the object world does not answer back. This is highly debatable given recent perspectives within science and technology studies, but it is interesting that Shanks and

Tilley adopted and modified Giddens double hermeneutic into a fourfold hermeneutic – but in such a way that actually bears no resemblance to Giddens concept of it. For Shanks and Tilley, archaeology was involved in a quadruple act of interpretation, by which they effectively meant the overcoming of four levels of distanciation: from our own disciplinary matrix, from our own social context, to an alien cultural context, and to a past cultural context (Shanks and Tilley 1987: 107–108). This was a somewhat befuddled attempt to expand Giddens's original notion, and few have actually adopted it in archaeology (but see Leone, in Hodder et al. 1995); indeed a faithful reading of Giddens' original articulation would ironically have excluded archaeology from the double hermeneutic, aligning it with the natural sciences.

On the other hand, it raises a problem which Shanks and Tilley perhaps should have addressed, namely, the question of whether objects do answer back. There are two issues here; the first concerns the potential of any object of study to be transformed by the act of study itself. This is a common enough property of any science, from quantum physics to archaeology. The second, more equivocal issue concerns a separation of meaning (humans, society) from materiality (objects, nature) as two different orders of phenomena. This separation of course can be traced right back to Dilthey and Weber who argued for two forms of knowledge and science, one which looked at reality from an external, causal perspective (natural science/explanation) and the other which looked at reality from an internal, meaning perspective (social science/interpretation). The distinction also lay at the basis of Hodder's contextual archaeology and adoption of Collingwood's approach to interpretation as empathetic understanding. In assuming this separation, Giddens was inevitably led to argue that only when the object of study has the same ontological status as the scientist, i.e., social phenomena, is there any possibility of answering back. Yet if one avoids the separation of reality into two orders, then no distinction between a single and double hermeneutic is necessary. Any science exhibits the dialectical characteristics of the double hermeneutic, but more importantly, the very term is perhaps redundant insofar as the concept of hermeneutics presupposes the distinction of two realities – meaning and materiality.

Future Directions

What is the future of archaeological interpretation? For some, interpretation has come to carry a somewhat negative connotation, whereby it implies nothing is ever what it seems: meaning is always hidden, always beneath the surface, and always one step away. In Freudian terms, a pipe is never just a pipe. This hermeneutics of suspicion (Olsen 2006), of depth (Thomas 2004b: 154–157) is largely the product of a post-structuralist influence on the concept of interpretation, whereby all meaning becomes completely unhinged from the materiality of the world as it is experienced and is one reason why interpretation itself has now become suspect. But the concept as originally formulated does not necessarily need to imply such a connotation. On the other hand, arguably the word interpretation today is often used loosely and interchangeably with explanation, as it once was before the processual-postprocessual wars of the 1980s and 1990s. This suggests two not necessarily unrelated possibilities: either people are just bored of epistemic subtleties or that the basis for the distinction between explanation and interpretation is simply no longer plausible. Is there really a divide between the natural and social sciences in terms of their forms of knowledge or orders of reality? Instead of just two sciences, many now argue for a more heterogeneous disunity to the sciences, while conversely, others in emphasizing the performative quality of the natural sciences reveal a continuity between science and other forms of cultural production. This is most apparent in work that comes under the rubric of postphenomenology, specifically the work of Don Idhe (1999, 2009). In archaeology, this shift has manifested itself through the recent rise of interest in a concept of materiality that does not separate itself from meaning, but as this literature reveals, the dichotomies generated from the last century are hard to shake off.

It may be some time yet before we see a resolution to this issue, but either way, the concept of interpretation is unlikely to remain unchanged. The extent to which Hodder's original adoption of the distinction between an internal and external type of understanding remains a valid one is hard to maintain today. Indeed, Hodder's later articulation of interpretation tended to focus more on the process or operation of the part-whole relation than this internal-external distinction, which is why some have suggested a greater commonality between interpretive and explanatory archaeologies. In many ways then, the concept of interpretation, as described in this chapter, is perhaps already redundant; if it has a future, it may not be one that separates it from explanation at least.

Introdução à Arqueologia Brasileira [Introduction to Brazilian Archaeology]

Marília Oliveira Calazans
University of Sao Paulo,
Sao Paulo, SP, Brazil

Basic Information

Introdução à Arqueologia Brasileira (Etnografia e História) (IAB-EH), by João Angyone Costa (Angyone Costa, Natal, 1888–1954), is

considered the first manual of Brazilian archaeology. The author argues that there was a need to systematize information related to archaeology, anthropology, and ethnology in Brazil, so that this information could be used as teaching material for the classes of the *Curso de Museus* offered by the *Museu Histórico Nacional* (Fig. 1).

IAB-EH underwent four editions that all sold remarkably well. The first one, with 348 illustrated pages, dates to 1934 and was published by the *Companhia Editora Nacional*, being part of the *Biblioteca Pedagógica Brasileira* collection. Due to it selling out quickly, the second edition was published only 4 years later, in 1938. Costa maintained the same format, only adding some comments, a subchapter on diet, an onomastic index, and a remissive index.

There are also two posthumous editions: 20 years after the second edition, and 4 years after the death of Angyone Costa, a third edition (1958) was published. The last edition contains a preface by his son, Dante Costa, to whom the first edition had been dedicated. Exhorting his father's qualities as a researcher, Dante emphasized the pioneering of this work, not only due to its dealing with archaeology but for placing the theme of the "Brazilian Indian" definitively in the science agenda. Finally, the fourth edition of 1980, composes volume 34 of the *Coleção Brasiliana* – a systematization of Brazilian studies published in partnership with the *Instituto* Nacional do Livro, of the former Ministério da Educação e Cultura.

The book manual is divided into four parts, which are *Part I: Elements for the study of Brazilian Archaeology*; *Part II: Archaeological Researches*; *Part III: Ethnographic and anthropologic elements necessary for the comprehension of Brazilian archaeology*; *Part IV: Morphology of the Tupi-guarani civilization, applicable, therefore, to other brazilic races*; and *Part V: Conclusions*. Altogether, the volume references 138 works by 106 authors, almost all of them written in Portuguese and published between 1844 and 1933. This reveals at the same time the range and the update of this work at the time. The annexed section provides notes on the 17 stamps that illustrate and inform about the distribution of indigenous people, ceramics, lithics, and rock engravings.

Angyone Costa was a secondary school teacher and a journalist and was a member of various scientific societies. He is also the author of *Civilização pré-colombiana no Brasil* (1935),

Introdução à Arqueologia Brasileira [Introduction to Brazilian Archaeology], Fig. 1 First edition (left) and fourth edition of *IAB-EH*

Arqueologia geral (1936), and *Migração e cultura indígena* (1939).

Major Impact

Although the author modestly declared the work being merely "an organization of indispensable elements for the study of Brazilian archaeology," *IAB-EH* does much more than present and compile studies on archaeology and ethnology. Its text resulted in the updating and reevaluation of a number of theories in vogue in the nineteenth century, among them are models of "savage" Indians versus "docile" Indians, which dominated the ethnographic accounts of naturalist travelers.

This helped to build the idea that archaeology was a discipline dedicated to the study of people that are "primitive," "uncivilized," or "in the stone age." The traits of civilization, through that perspective, were the use of clothes, the sophistication of artifacts, and the domestication of animals and plants. Indians were also qualified due to their physical characteristics such as color, hair, stature, and the shape of their noses.

The scientific authority which surrounds *IAB-EH*, used as a work of reference by many young students, resulted in Costa's perspectives being disseminated in a large number of scientific works in the twentieth century and, in a way, remains present until today. This can be seen in Costa's classification of research *sambaquis* (shell mounds) in the nineteenth century distinguishing three interpretative currents. Once the author had classified those three trends – stating that there were scientists who understood the shell mounds rather as a natural phenomenon, as archaeological sites, or a mix of those – a number of archaeologists repeated this judgment, even though it does not confirm itself factually.

For beyond the shell mound sites, caves, lithic stations, and stilt dwellings are also inserted into his data collection of archaeological sites. Other themes of the nineteenth century, however, were abandoned. This was the case of the mythic lost civilizations and the Viking and Phoenician inscriptions, which were themes that had inspired a number of studies in the prior century, but Costa considered these suspicious, due to a lack of scientific evidence. While other general books were published years or decades later, *IAB-EH* stands both as a great pioneer work on the theme of Brazilian archaeology and the disseminator of an idea about what Brazilian archaeology was at its very beginning.

Iran: Heritage Preservation and Tourism

Azwin Azny Aksan
Department of Recreation, Sport and Tourism, University of Illinois at Urbana-Champaign, Champaign, IL, USA

Introduction and Historical Background

This entry seeks to provide empirical evidence concerning heritage preservation in the Islamic Republic of Iran. A brief description of the country's tourism industry is also presented as this relates to the cultural heritage.

Until 1935, Iran was historically referred to as Persia when Reza Shah Pahlavi formally announced to call the country by its *native* name, Iran. Under the leadership of Ayatollah Khomeini, the current Islamic Republic of Iran was founded in 1979. Iran has an impressive history and fascinating culture. The Iranians are very proud of their culture and history. It is important to note that Iran is not an Arab country. Iran comes from the word "Aryan" with its official language being Farsi, an Indo-European language. Although Iran is portrayed in the media as a society of purely Islamic fundamentalists, the country is also comprised of people practicing other religions making it, in reality, a multicultural national entity.

Iran's heritage is very represented on the UNESCO World Heritage List with 13 cultural sites. Clearly, Iran has an abundant wealth of cultural assets of the pre-Islamic and Islamic eras and thus great potential for tourism. Although tourism to Iran is restricted or difficult due to its political situation and strict Islamic practice, Iran nevertheless has recorded a significant increase in its inbound tourist arrivals. More than 1.6 million international visitors were generated in 2004.

Key Issues

Heritage Management, Policy, and Laws

The *Iran Cultural Heritage, Handicrafts, and Tourism Organization* (ICHHTO) is an organization in charge of the protection of Iranian monuments. Apart from that, the agency is also responsible for overseeing the country's heritage and tourism movement. All projects concerning the protection of monuments in Iran must be in accordance with the provisions of the law and must be approved by ICHHTO. However, I have not identified the specific law concerning this protection.

All nominated properties to the World Heritage List are protected under the Iranian legislation since 1932. Apparently, according to the current law, special protection provisions are in place for the property, the buffer zone and for a wider area called the "landscape zone." The High Technical Council of ICHHTO is responsible for the management of these protected monuments by allocating funding for major conservation works. Minor works and maintenance is ensured by a steering committee (Table 1).

It is complicated and difficult to distinguish the differences in functions and status between the ICHHTO, ICTHO, and ICHO. O'Gorman et al. (2007), in their article on central control and indigeneity of tourism in Iran, state that the growing links between tourism and the protection of

Iran: Heritage Preservation and Tourism, Table 1 Organizations responsible for the management of heritage and tourism in Iran

Iran Tourism and Touring Organization (ITTO)

Iranian Cultural Heritage Organization (ICHO)
Cultural Heritage and Tourism Organization (ICHTO)
Research Center for Conservation of Cultural Relics
Iran Heritage Foundation (IHF)
ICHO Anthropology Research Center
Technical Office for Preservation Projects of ICHO
Research Center of the Traditional Arts

Iran's national cultural heritage were reinforced in 2005 with the merger of *Iran Touring and Tourism Organization* (ITTO) and *Iran Cultural Heritage Organization* (ICHO) to form the *Iran Cultural Heritage and Tourism Organization* (ICHTO). It is interesting to note the way heritage and tourism is viewed based on the formation of these organizations. It appears that the country is aware of the significance of tourism and recognizes the importance of preserving heritage and cultural sites for that sector.

Another organization identified is the *Iranian Cultural Heritage Organization* (ICHO), which is also a governmental agency responsible for carrying out research, conservation, rehabilitation, presentation, and education concerning the cultural patrimony of Iran. It was mentioned earlier that this organization has been merged with ITTO to form the ICHTO. However, it is still very complicated to understand the heritage management of the country. Initially, the agency is responsible in formulating policy for cultural and heritage of Iran. It was also mentioned that the subdivision of ICHO, the *ICHO's Anthropological Research Center*, is made up of four research departments: social anthropology, ecological anthropology, ritual anthropology, and traditional arts. Their main responsibility is to carry out research in the various domains of Iran's intangible cultural heritage.

There is also another organization which, if not carefully read, may be mistaken as the earlier organization mentioned above, and it is unclear at this moment if both exist. *Iran's Cultural Heritage, Tourism and Handicrafts Organization* (ICTHO) is an agency responsible for the establishment and development of tourism in Iran. ICTHO is an educational and research institution overseeing a variety of museum complexes throughout Iran. Established in 1985, it is administered and funded by the government of Iran.

The *Iran Heritage Foundation* (IHF) is a nonpolitical UK-registered charity with the mission to promote and preserve the history, languages, and cultures of Iran. It can be assumed here that this may be a nongovernmental and nonprofit agency which is aimed at organizing diverse activities of cultural or scholarly merit which include academic research, publishing, and fellowships. IHF initiates a wide range of activities intended to facilitate the study of Iran's history and culture, both among academics and the wider community. Their main source of funding is the annual contribution pledged by trustees and patrons as well as fund-raising events. They encourage business and individual sponsorships but they accept no financial support from any government organizations or lobbying groups.

Iran Stolen Heritage

The *Iran Heritage* site (http://www.iran-heritage.org/index.htm) is a resource for anyone interested in preserving the heritage of Iran. The main goal of this site is to document stolen properties which have been transferred to locations and museums worldwide. These archaeological finds belong to Iran and its people. According to the UNESCO Convention of 1970, legal actions can be taken to return the stolen properties to Iran or Iranian museums anywhere in the world. The association listed three stolen Iran heritages worldwide on their website. The first one was found at the New York Metropolitan Museum of the United States. Another stolen heritage was reported in the Los Angeles County Museum of Art. According to the site, the museum paid $40 million to a private collector to purchase the stolen Iranian Heritage. The last reported stolen heritage was found at the Louvre Museum in Paris, France, and the British Museum, London, England – but no information was available on this. Another important purpose of this site is to raise the awareness of Iran's culture and natural resources.

World Heritage Sites

At present, there are 13 cultural sites of Iran listed on the World Heritage List. The table below provides the list of Iran's cultural properties listed in the World Heritage Sites. Out of those, one is listed as site in danger: Bam and its cultural landscape (Table 2).

Meidan Emam, Esfahan, was the first Iranian site inscribed on the UNESCO World Heritage List (in 1979). Known for its Royal Mosque, the site is an impressive testimony to the level of social and cultural life in Persia during the Safawid period (UNESCO). The center of the city was dominated by a vast Royal Square and so large that it was called "the image of the world."

Tabriz Historic Bazaar Complex	Cultural, 2010
The Persian Garden	Cultural, 2011

Source: UNESCO World Heritage List. Available at: http://whc.unesco.org/en/list

Persepolis was also inscribed in 1979. It was built on an immense half-artificial, half-natural terrace, where the "king of kings" created an impressive palace complex inspired by Mesopotamian models.

Another cultural property inscribed that same year is the *Tchogha Zanbil*, which is the ruins of the holy city of the Kingdom of Elam.

The archaeological site of *Takht-e Soleyman*, situated in a valley set in a volcanic mountain region, has an important symbolic significance and an outstanding ensemble of royal architecture situated in Azerbaijan province. Located about 750 km from the capital city of Tehran, the site is well known for heritage tourism among international visitors.

Pasargadae was the first dynastic capital of the Achaemenid Empire. Its palaces, gardens, and the mausoleum of Cyrus are outstanding testimonies of the Persian civilization. The property was inscribed in 2004 based on criteria I, II, III, and IV.

Soltaniyeh, situated in the northwest province of Zanjan, is another important achievement of the Persian Islamic architecture. The property has been described as "anticipating the Taj Mahal." It is believed that the site was occupied at least from the first millennium BCE.

Bisotun is located along the ancient trade route linking the Iranian high plateau with Mesopotamia. The site includes remains from prehistoric times to the Median, Achaemenid, Sassanian, and Ilkhanid periods. The principal monument is a bas-relief ordered by and featuring Darius I, the Great, when he ascended to the throne of the Persian Empire in 521 BCE.

The *Armenian Monastic Ensembles of Iran*, situated in the northwest of the country, consists of three monastic ensembles of the Armenian Christian faith: St Thaddeus and St Stepanos and the Chapel of Dzordzor. *Shushtar Historical Hydraulic System* was inscribed at the same time.

Sheikh Safi al-din Khānegāh and Shrine Ensemble in Ardabil incorporates a route to reach the shrine of the Sheikh, divided into seven segments and constituting a rare ensemble of elements of medieval Islamic architecture.

The *Tabriz Historic Bazaar Complex* is one of the most important commercial centers on the Silk Road. The complex has been one of the most important international places for commercial and cultural interchange. It was officially protected in 1975.

The Persian Garden includes nine gardens in nine provinces of Iran. As explained in the UNESCO website, "They exemplify the diversity of Persian garden designs that evolved and adapted to different climate conditions while retaining principles that have their roots in the times of Cyrus the Great, 6th century… [and] influenced the art of garden design as far as India and Spain."

Heritage in Danger: Bam and Its Cultural Landscape

Bam and its cultural landscape is the only property of Iran inscribed to the World Heritage List as heritage in danger. It is situated in a desert environment on the southern edge of the Iranian high plateau and was known for the production of silk and cotton garments. The site was submitted to UNESCO in 2004 after it was affected by the 6.2 magnitude earthquake in 2003, which destroyed most buildings of the city and killed more than 26,000 people. The Citadel was also seriously damaged. The government is still gathering efforts to revive this significant heritage property.

According to the official tourism website, this site receives substantial number of tourists every year. Being listed as heritage in danger does not mean the site will result in poor visitation. In fact, it would give more reasons for people to visit a site.

Properties on Tentative List

Iran has more than 50 sites submitted to UNESCO Tentative List! Most of these sites are cultural sites. In 1997, Iran submitted seven sites to UNESCO and is still awaiting approval into the premier list: Mosque Esfahan, Historic ensemble of Qasr-e Shirin, and Firuzabad Ensemble just to name a few. The government believes that the Tentative List will help them maintain sites of significance from further destruction and damage. In 2007, Iran submitted 40 cultural and natural sites to be listed as World Heritage Sites of UNESCO. Eleven more sites were submitted in 2008 making the total altogether 56 tentative sites.

Iran as a Tourism Destination

Tourism is undoubtedly an important industry for economic development of Iran. Before 1979, Iran was a well-known destination due to its impressive history and ancient civilization. Its attractive natural and historical sites are rated among the top ranked in the world (ITTO). The 2005 20-year Tourism Development Master Plan with the assistance of World Tourism Organization (WTO) is one effort indicating how serious the Iran government was on investing in tourism. UNESCO ranks Iran seventh in the world in terms of possessing historical monuments, museums, and other cultural attractions. This is a positive indication of how Iran can explore its tourism potential and attracts more international tourism. However, it has been a rather difficult process for tourism to flourish in Iran. Poor advertising, internal and international political instability creating an image of Iran as an unsafe country, and its negative public image in some parts of the world have hindered the growth of tourism. Perhaps a greater difficulty is that of getting an entry visa. At present, countries with no visa entry requirements are Bosnia-Herzegovina, Croatia, Japan, Turkey, and Saudi Arabia (ITTO).

In addition, the prohibition of alcohol and the strict Islamic women's dress code discourage tourism from the West. It is reported that tour operators in some countries are unwilling to promote Iran due to these circumstances. Yet many tourists from outside the Islamic world are undiscourage and Iran has somehow strategize its tourism campaigns to countries willing to accept these strict regulations.

Tourism will help enhance Iran's image internationally and, perhaps, change people's perceptions of its country.

In its further effort to promote tourism, Iran has established a *Special Economic Zone* and a *Free-Trade Industrial Zone*. These free zones are designed as an incentive for foreign investments. These zones provides facilities such as proper employment regulations, 15 years tax exemption, national and international banking facilities, no currency restrictions, abundance of energy sources, labor of all skill levels, no visa entry requirements, and tourist attractions (WTO 2002). The incentives provided in these zones have attracted many foreign investments.

Approximately 1.8% of national employment in Iran is generated in the tourism sector which is slated to increase to 10% in the next five years. In 2009, tourism attracted 2.3 million people to Iran. The tourists' arrival data or statistics are not available on Iran's leading tourism website. Countries such as Japan, Germany, and Turkey, that have good relations with Iran, are some of their main target markets. A study by Vafadari and Cooper (2007) on Japan and Iran's relationship in tourism reported that the Japanese with strong interest in heritage tourism constitute one of the most important tourism markets for Iran. Iran plans to have 20 million tourists annually by 2015. Cultural and heritage attractions constitute the focal point of Iran tourism promotion and marketing. According to their official tourism website, Iran Travel and Tourism Organization (online), 70% of Iran's tourists are from Europe. However, it was reported that tourists' arrivals in Iran faced a decline in 2008. Iran has been criticized as having a negative image internationally due to its political tension with the western governments. The country also has a reputation for supporting various elements of Islamic extremism.

Domestic tourism in Iran, however, has remained strong despite the decline in

international arrivals in 2008. Many domestic trips reported were among the religious visits or visiting family and friends (VFR).

Safeguarding Intangible Cultural Heritage and Developing Ecotourism

Although this encyclopedia is concerned with archaeology, when dealing with cultural heritage and world heritage the intangible must also be recognized. Moreover, ecotourism immediately implicates Iran's living cultural heritage.

One area considered for further expansion in the tourism sector in Iran is ecotourism. Iran has an established image of its heritage attractions and this has attracted many visitors with such interest. In expanding its tourism and exploring further potential in tourism, Iran has recently showed interest in investing in ecotourism. An initial project to realize this plan was to develop and preserve Masuleh, a village rich in tangible and intangible heritage. Masuleh is located in a scenic valley surrounded by snow-capped mountains in northeastern Iran. The village is a site of the UNESCO and the Iran Touring and Tourism Organization (ITTO) project in Iran. Notable for its traditional wooden buildings, clustered on the northern slopes of the valley, Masuleh is registered as national cultural and natural heritage in Iran. The project is aimed at encouraging community participation in the area's tourism development and helping to generate employment opportunities.

In its effort to safeguarding intangible heritage, the government of the Islamic Republic of Iran has passed several laws pertaining to aspects and the manner in which intangible heritage should be preserved. The following table provides the list of laws and acts about Iran's effort in protecting their intangible heritage (Table 3).

The Intangible Cultural Heritage list is composed of intangible heritage elements that concern communities and require urgent measures to keep them alive (UNESCO 2003). UNESCO defines intangible heritage as living traditions that are passed on from one generation to another. These include spoken traditions, festivals, performing arts, social ceremonies, and cultural knowledge. Inscriptions on the list help mobilize international cooperation and assistance for stakeholders to undertake appropriate safeguarding measures (Table 4).

Future Directions

Iran is a large country with numerous attractions that appeal to tourists particularly its rich heritage and cultural assets. Apart from its economic potential, tourism and cultural exchange will promote prosperity and understanding of other countries towards Iran. The 2005 Tourism Development Master Plan (WTO 2002) has in many ways helped justify Iran's tourism direction and attracted many stakeholders, foreign expertise and investors to boost up the country's tourism industry. Iran's potential in becoming a leading tourism destination is very strong considering the amount of heritage sites the country own and is maintaining.

The country receives great attention from UNESCO on preserving its heritage. Despite some of the major issues and challenges facing its tourism industry, Iran continues to receive tourists particularly interested with its cultural, history, and heritage endeavors. Iran is now gradually dealing with its challenges and limitations

facing its tourism industry. Issues such as the use of "hijab" among women tourists and prohibiting alcohol have invited much debate over the years. The government is also planning to extend its free-trade zones to the main land instead of just limiting it to the Iranian islands in order to distribute an equal share of its tourism economic benefits. The government has also taken measures to facilitate inbound tourism by easing visa issuance on arrival to many nationalities.

Historically, the war with Iraq impacted the country's tourism growth and a major decline in tourism arrivals was reported for Iran. Despite such turndown in tourism, Iran has instead focused its policy on selective markets with emphasis on its Islamic-Iranian civilization. Tourism policy was formulated with the aim to achieve Islamic unity among the Muslim nations through tourist exchanges. Although the policy was not aimed to attract tourists on a global scale, it was enough to boost tourism for Iran.

In recent years, the negative image of Iran imposed by international media has also played a major factor in the declining international tourism arrivals. The Middle East is often described as an unsafe place for tourists in general. In its effort to support tourism in the country and internationally, Iran's government has also given substantial responsibilities to the private sector in developing the industry particularly to preserve and restore historical monuments, cultural, and heritage products and tourism facilities, limiting its own role to tourism policy making and strategic planning (WTO 2002).

Apart from efforts in tourism, it is also important for Iran to enrich its management efforts of its heritage sites. This will require further research over the existing situation of Iran's heritage management and the impacts tourism may bring to the country's heritage sites.

Iran: Islamic Archaeology

Martina Rugiadi
The Metropolitan Museum of Art, New York, NY, USA

Introduction

Islamic archaeology is a discipline characterized by an inaccurate and problematic definition. The chronological and geographical extent of Islamic history and the cultural, ethnic, and religious peculiarities of the territories ruled by Islamic authorities prevent the imposition of a conclusive definition – to the extent that this problem has become an object of research in itself. In the case of Islamic archaeology in Iran, additional issues relate to the nature of the birth and development of Islamic archaeology and the cultural peculiarities of the country, including its historical–political vicissitudes. For example, we must take into consideration the privileged role of the pre-Islamic past in shaping the national identity of Iran, as well as the historic influence of Westerners in the country.

Definition

Islamic archaeology in Iran involves the exploration of landscapes and excavation of archaeological sites as well as the study of monuments and artifacts that have been produced since the Islamic conquests. The Islamic expansion started in Iran in the seventh century and is conventionally accepted as having ended with the defeat of the Sasanian Empire in 641. Research into the Islamic period relates to elements and structures (such as mosques, madrasas, graveyards and funerary monuments, government buildings, monetization) that directly represent Islam as a religious and institutional entity or elements and structures (such as the water supply system, communications network, agricultural exploitation, production and commercialization of goods) that involve the socioeconomic organization of urban and rural territories, connected with either the Muslim majority or minor religious groups such as Christians, Zoroastrians, Jews, and minor Islamic sects such as the so-called Assassins.

Historical Background

An interest in the antiquities of Iran's Islamic period is demonstrated by the documentation of monuments and sites by occasional Western travellers since the seventeenth century, becoming more widespread in the late nineteenth century stimulated by the antiquarian appeal of the artifacts shown at Universal Exhibitions in Europe and America (mostly in Paris in 1867, 1878, and 1889). The antiquities market's growing demand for these artifacts led to excavations, generally authorized by the government, in search of objects of commercial value. Antiquarians themselves conducted such excavations. Among them were many Europeans, such as C. Vignier and G. Demotte, and Armenians such as the Kelekian and Kevorkian families. Excavations were also carried out illegally. These lucrative commercial activities had harmful effects on archaeological sites: Nishapur, Rayy, Sirjan, and Sava are among those damaged by such activities (Vernoit 2000). The commercial value of the artifacts also led to forgery, such as the case of some of Rayy's "Buyid" textiles.

The close relationship between antiquarians and art historians, together with the supremacy of history of art over archaeology in the academic context of the time, favored a historical–artistic approach to the study of artifacts of the Islamic period. This approach focused on decorative motifs, iconography, and the presence of inscriptions on decontextualized objects and legitimized the unscientific excavation of archaeological sites. In addition, this approach was contaminated by the ethnocentric and colonial tendencies of the cultural and political climate. The assumed superiority of Indo-Europeans over Arab Semites had long-term consequences in archaeology, for instance, in the preconceived attribution to Iran of stylistic and technical innovations in ceramic production.

The principal concern of the first archaeologists in Iran was to excavate the many important sites of the pre-Islamic period. Islamic strata encountered during excavations were usually ignored and often left unrecorded. Accordingly, it is not surprising that Islamic archaeology in Iran had difficulties in establishing itself as an autonomous discipline and that scientifically conducted archaeological excavations of Islamic sites started relatively late.

Between 1885 and 1931, when France had a monopoly over the awarding of concessions to excavate in Iran, the most excavated archaeological site was Susa, located in the southwest of the country. Archaeological surveys were carried out by the *Délégation archéologique française en Perse* (subsequently renamed *en Iran*, DAFI) since its foundation in 1897 and continued with few interruptions until 1979. The task of these surveys was to collect as many archaeological finds as possible. There was no interest in stratigraphy or context. Moreover, the search did not address the Islamic period. Nevertheless, the high number of Islamic ceramics found attracted the attention of experts, including G. Migeon, M. Pézard, and R. Koechlin.

Research on monuments conducted without excavation by scholars such as F. Sarre (1901–1910) and E. Diez (1918) provided a scientific basis for the development of Islamic archaeology in Iran at the beginning of the twentieth century. Particularly relevant is the publication of the monumental *A Survey of Persian Art from Prehistoric Times to the Present*, edited by A.U. Pope and P. Ackermann (1938–1939), which includes studies on architecture and artifacts of the Islamic period in Iran by authors including Godard, Herzfeld, Monneret de Villard, Schmidt, Schroeder, Siroux, Smith, and Wilber; the publication offers a complete overview of scientific research conducted in the region. The first specialized journals appeared in the same period, such as *Āthār-é Īrān* (Service Archéologique de l'Iran, 1936–1949, founded by Godard) and the *Archäologische Mitteilungen aus Iran* (Berlin, 1929–1937 and 1968–), publishing articles that contributed to the evolution of the discipline.

The Metropolitan Museum of New York started its first archaeological excavation of a site of the Islamic period in the 1930s, at Nishapur in Khorasan (conducted by J. Upton, W. Hauser and C.K. Wilkinson; see below). Other excavations that aimed to understand the pre-Islamic and succeeding phases were conducted by the Metropolitan Museum at Qasr-i Abu Nasr, close to Shiraz (from 1932); furthermore, E. Herzfeld started excavations at Istakhr, which were continued by E.F. Schmidt (1932–1937; see below) who was also working at Rayy (1932–1936). The archaeological results concerning these sites' Islamic levels have been published scarcely or not at all; their publication has been restarted recently but has not been completed for all sites (for Qasr-i Abu Nasr, see Whitcomb 1985; for Rayy, see Keall 1979; for the other sites see below).

The excavations at Nishapur investigated several *tepe*s, the most important of which are Tepe Madrasa, Sabz Pushan, "Vineyard" Tepe, and Qanat Tepe, uncovering houses, mosques (the *mihrab* always having a rectangular section), and *hammam*s. Almost all of these features have been dated between the ninth and twelfth centuries (Wilkinson 1987). The remains of architectural decoration are remarkable, particularly the mural paintings (these include ornamentations of animated vegetal motifs, imitations of marble panelling, and depiction of characters such as a knight and an attendant), the carved and painted stucco facing, and the baked-brick panels. Many houses had small *mihrab*s set into the walls and rooms set around a central courtyard, often with a colonnade. In subsequent phases, many of the rooms were divided. Water was supplied through canals. A mosque with a (later) minaret of octagonal section was brought to light at Tepe Madrasa, and various phases of this rectangular-planned mosque, with courtyard, were identified. Numismatic evidence indicates a *terminus post quem* of 785 for the earliest phase. An architectural complex composed of various profusely decorated rooms was also located at Tepe Madrasa. This was probably a palatial or governmental structure (despite the lack of a normally typical symmetrical framework). The finding of ceramic fragments

spanning the eighth to the fourteenth centuries in the remains of a pavilion with dome shows continuity in the use of the complex in this tepe after the Mongol invasion. At Qanat Tepe the excavations brought to light a mosque of at least the tenth century, with rectangular plan and two central pillars, a *hammam* with an octagonal *calidarium*, and remains of mural painting probably of Seljuk date.

Archaeological research on the city of Istakhr in the region of Fars has investigated the transition from the Sasanian period to that following the Islamic conquest of the seventh century. The results confirm that the city was prosperous during the ninth to tenth century and almost totally abandoned at the beginning of the eleventh century (Whitcomb 1979). During the seventh century, the urban center had been moved within the broad city walls that surrounded the Sasanian city. The new urban installation was characterized by the same orientation as the seventh-century congregational mosque. The hypostyle mosque had been built with spoliated stone material probably of the Achaemenid period and had columns with tauriform capitals and a painted *mihrab* decorated with stucco. The excavations also uncovered a row of bazar shops and three private houses, the houses having a narrow entrance with rectangular buttress and rooms over the central court, and a productive area with kilns. The interactions between the urban site and surrounding territory as well as agricultural exploitation and water supply in the region have been investigated by mean of surveys in the Marvdasht valley.

The systematic documentation of Iran's archaeological sites through aerial photography was undertaken by E.F. Schmidt and his wife M.H. Warden and published under his name only in 1940 (Schmidt 1940). This publication is still important and includes some Islamic sites.

Following a break due to World War II, renewed archaeological activities in Iran showed greater awareness of historical enquiry, applying excavation techniques to investigate the phases following the Islamic conquest and increasing the accuracy of their documentation. The 1960s and 1970s were a time of important excavations, bringing a considerable increase in knowledge about different Islamic periods in Iran, in particular that corresponding to Seljuk sovereignty. The most significant work saw renewed interest in Susa and Takht-e Sulayman, Siraf, the Friday Mosque of Isfahan, and Ghubayra (see below). In the same year, the publication of two major journals began: *Iran* (British Institute of Persian Studies, 1963–) and the *Cahiers de la Délégation Archéologique Française en Iran* (1971–).

Research in Susa recommenced in 1946 and was directed by R. Ghirshman until 1967. During this period, methods of excavation and recording were modified in order to consider the Islamic period. Archaeologists specializing in the Islamic period that undertook research under the direction of J. Perrot between 1967 and 1979 include M. Rosen-Ayalon, C. Hardy, M. Kervran, and A. Rougelle. The study and publication of the Islamic phases of some areas of the site and associated materials was commissioned (Hardy-Guilbert 2005). Continued use of the site is testified by the private and public buildings of the seventh century, in the three terraced *tepe*s called Apadana, Royal City, and City of the Craftsmen, according to the Achaemenid remains. The private houses became progressively bigger towards Apadana's *tepe* and are characterized by a central court that can have a colonnade or one or more *iwan* according to the socioeconomic status of the family; bathrooms and lavatories were connected to a sewage system. Motifs on stucco-decorated columns and in niches and apertures occurred in the grander buildings. The Friday Mosque, built in 639, had a court with columns around three sides and a prayer room without *mihrab*, which formed part of the significant enlargement that occurred around 700, to which also belonged the architectural decorations in carved stucco and baked brick with inscriptions in kufic. A minaret was also found during the excavations.

A large building was located close to the mosque, probably a *khangah* (monastery). It contained two structures at the sides of the entrance and a rectangular central court with access to the various rooms. A significant quantity of ceramics dated from the beginning of the eleventh century indicates that the building had been used as a dump since this time. The growth of the

city between the end of the ninth century and the beginning of the tenth century included the integration of the residential areas into the urban fabric following an orientation determined by the Achaemenid buildings. Susa was already equipped with a public *hammam* at this time. During the tenth century, the Apadana and the Royal City were abandoned, although the areas to the east and west continued to be inhabited until the thirteenth century. Much of the evidence was linked to the productive economy of the city, mostly related to ceramic and glass manufacturing and to sugar production from the tenth to the thirteenth century.

The German Archaeological Institute conducted excavations of the Ilkhanid site of Takht-e Sulayman in Azerbaijan from 1959 to 1978 (Naumann 1976). This included excavating the Ilkhanid palatine complex, which was built during the reign of Abaqa Khan (1265–1282), as indicated by finds of dated tiles, near a water basin on the site of a Sasanid Zoroastrian sanctuary. The remains of the Ilkhanid period, including the city walls (built over the Sasanid walls) and the palatine complex, are characterized by a north–south axis. The palace was built around the water basin. It had four *iwan*s with the throne hall located behind the northern *iwan*. The architectural decoration revealed stuccoes (including *muqarnas*), paintings, and, above all, tiles of various shapes, decorated with figurative motifs using techniques such as lustre and *lajvardina*. The tiles were combined according to complex geometrical schemes to produce high dadoes. The Ilkhanid court occupied the complex only periodically, regularly moving from place to place, using temporary campsites.

From 1966, the British Institute of Persian Studies undertook an excavation, among the most fruitful in terms of results and publications, of the port city of Siraf on the Persian Gulf, directed by Whitehouse until 1973 (see the reports published in *Iran* from 1968 to 1974; also Whitehouse 1980). The excavations revealed several areas with private houses, a bazar, small mosques, the congregational mosque, and the remains of city walls and highlighted the evolution of the urban structure over the period of the city's prosperity until the twelfth century. The most ancient phase of the Friday Mosque (dated to the early 9th c. according to numismatic evidence) took the form of a hypostyle prayer room, with a rectangular *mihrab*, and a courtyard with colonnade and a minaret. Various extensions, mostly concerning the prayer room, characterize the subsequent phases of the building's use, dated to the ninth or tenth century. The findings indicate the use of decorations in stucco, such as sawtooth crenellations decorated with vegetal motifs. Of great interest are the private houses, dated up to the eleventh century and generally provided with a central court onto which the rooms open; the richest houses, mainly in residential areas, have a quadrangular plan with buttress, the internal walls often covered in plaster and stuccoes. Wells and tanks guaranteed the water supply, and the houses were equipped with sewage systems. The excavated area also included a large public building the date of which seems to be prior to the mid-eleventh century. This building did not have a central court but probably had a second storey; however, its function is still unknown. Metallic production waste and the discovery of an area with kilns and structures for ceramic production provide a better understanding of the city's economy, while various finds of Chinese and Southeast Asian fragments of ceramics tell us something about its commercial role (Tampoe 1989; see also Priestman and Kennet 2002 for studies of ceramics from this and other sites in the region).

W. Kleiss conducted research in Iran from the 1960s with the aim of locating monuments (including bridges and dams); his various articles were published in *Archäologische Mitteilungen aus Iran*. The architectural documentation and research undertaken by R. Hillenbrand is of great relevance, the object of his investigation being the identification of regional styles of the Seljuk period (articles published in *Oriental Art* 1972 and *Iran* 1972, 1976, 1987). Also important was the finding of two important funeral towers in Kharraqan (dated to the end of the eleventh century) by D. Stronach and C. Young in northwestern Iran (1966). The various field surveys undertaken include W.M. Sumner's research in Fars, through which he created an archaeological

map that is still of fundamental importance for the Islamic period (*Tell-i Malyan and Chronology of the Kur River Basin*, 1972); the archaeological surveys conducted by A. Williamson in southeastern Iran, who also excavated small trenches (e.g., at Sirjan), aimed at the investigation of commercial and distribution routes for ceramics during Islamic periods (see Williamson 1987; Morgan and Leatherby 1987).

Excavations were conducted in Ghubayra, southeastern Iran, from 1971 to 1976 (Bivar 2000). Italian restorers from the *Istituto italiano per il Medio ed Estremo Oriente* (IsMEO, later IsIAO) were in charge of restorations, undertaking research at the same time, sometimes including the excavation of sondages, in order to conduct more accurate conservation. They worked mainly on religious monuments of the Seljuk period and various monuments of the Safavid and Qajar periods, mostly in Isfahan and the provinces of central Iran (among others, the mosque of Bersian, Ali Qapu's palace, Chehel Sotun's pavilion, and the door of the great bazar of Isfahan; see Zander 1980). The restoration of the Friday Mosque of Isfahan conducted by Galdieri (1973) from 1970 led to the identification of various pre-Seljuk phases, such as the Buyid and two Abbasid phases. These results indicated the need to proceed with detailed archaeological investigations, which were conducted by U. Scerrato from 1972 to 1978. Preliminary reports on what is considered to be the most representative monument of the architectonical and artistic evolution of Islamic Iran were published in the journal *East and West* (Scerrato 1973–1979). Research identified the various phases of construction but also found a Sasanid or proto-Islamic settlement and a more ancient mosque with an orientation different to that of the present. The earlier building can be dated to 772 based on historical sources. Excavations brought to light the *qibli* wall with a rectangular *mihrab*, both covered with decorated stuccoes, as well as some of the baked-brick columns that confirm the building's hypostyle structure. In the same area, one level down, a column covered in stucco with decorations in Sasanid style was found. It has a different orientation again but no evidence has been found of the nature of the building to which it belonged. The first mosque was destroyed in 842 and replaced with a wider building with a different orientation, comprising a hypostyle plan and central court with colonnade. All subsequent alterations had this building as their starting point: the addition of a row of baked-brick pillars resulted in a smaller court in the Buyid period (tenth century); two big pavilions with domes were built between 1088 and 1092 during the reign of the Seljuk sultan Malik Shah. Investigations revealed that the first pavilion, located in the north on the same axis as the mosque, was initially outside the building. At a later time, it was linked to it through hypostyle rooms. The second pavilion, located in the same area as the *mihrab*, was built after the demolition of the previous prayer room; this pavilion was also originally an independent structure. After these alterations, the four *iwan*s were added.

Important excavations conducted in the 1970s include finding the Ilkhanid astronomical observatory in Maragha, commissioned by Hülägü in 1258 at the request of the scholar Nasir al-Din Tusi (excavations 1972–1976; Vardjavand 1979); the excavations in Sultaniyya, the new capital founded by Ülgiaytü in 1307 (Gandjavi 1979); and excavations at Gurgan, on the Caspian Sea, where various buildings were found, including a mosque dated to the beginning of the thirteenth century, a Seljuk *hammam*, and kilns for the production of metal, glass, and mostly ceramics (Kiani 1984).

Key Issues/Current Debates

In recent decades archaeological work in Iran has been forestalled by social and political disruption. The Islamic revolution of 1979 called a halt to archaeological surveys conducted by foreigners in Iran, while the consequences of the Iran–Iraq war prevented the rise of Iranian archaeology for a long time. Both circumstances began to change in the 1990s with the appearance of Iranian teams (such as the excavations conducted by Moussavi in Nishapur, 1995–2005) and the first cooperative projects between foreigners and Iranian

archaeologists. Examples of such collaborations include documenting and archiving the finds from the archaeological survey conducted at the Friday Mosque of Isfahan in the 1970s (codirected by U. Scerrato in 2000 and by B. Genito from 2002 to 2010; Genito and Saeidi Anaraki 2011), the French excavations in Nishapur (codirected by M. Kervran, 2005–2006; Fouache et al. 2011), and the German excavations of the Friday Mosque of Golpayegan (codirector L. Korn; Korn in press).

Collaborative activities are strictly dependent on the variability of political and diplomatic relations between countries and as such can be limited. In terms of projects excavating sites of the Islamic period promoted by Iranian institutions, these are few and difficult to access (the few publications, in Persian, are spread among the various but not very widely disseminated Iranian archaeological journals). The excavations conducted in the Ismaili fortress of Alamut (directed by H. Chubak) revealed a reception room with a small *iwan* opening onto a room characterized by a central depression (maybe a pool? Chubak 2009). The excavations of the palatine complex of Sarvestan, east of Shiraz (conducted by A.R. Askari), are also relevant. This site is now attributed to the ninth century, rather than to the Sasanian period, according to the ceramics found (Askari Chāverdi 2009–2010; see also Bier 1986 with previous bibliography).

Up to the present day, the main focus of archaeological surveys in Iran has been urban areas, particularly religious buildings. The relatively low number of such archaeological sites that have been investigated means that our knowledge is restricted to the limited data collected and to analyses of the different regional contexts of the various sites. In addition to these sites, it is important to recognize others that are mostly pre-Islamic but have later phases that have not been examined in depth, as well as a number of relatively minor sites (Rugiadi 2005). Taken together, these represent an essential base for future research. Many religious monuments, especially those built since the Seljuk period, have been the focus of architectural-stylistic studies instead of archaeological excavations. However, the continuous and often drastic repairs conducted on most of the monuments, especially the religious ones, make research on these structures particularly difficult.

Archaeological surveys in rural areas and studies of the dynamics of landscape utilization at regional level, including the analysis of communications and exploitation of water resources, are still underdeveloped (Williamson 1987); some data can, however, be obtained from archaeological surveys focusing on evidence of the various pre-Islamic periods (such as Sumner 1972). One of the most stimulating topics connected with Islamic archaeology in Iran, for which further research is necessary, concerns the evolution that occurred in urban, architectural, historical, and artistic areas after the Islamic conquest.

Iraq: Archaeological Heritage

Maria Theresia Starzmann
Department of Anthropology, McGill University, Montreal, QC, Canada

Brief Definition of the Topic

The archaeological heritage of Iraq comprises antique remains, including sites, architectural features, and artifacts, for which excavations, surveys, and remote sensing are the main methods of discovery. Broadly speaking, archaeological heritage constitutes traces of past human existence, bearing witness to various forms of past social life. To date, more than 10,000 sites and monuments have been designated as part of the

archaeological heritage of Iraq, and many more sites exist that have not yet been excavated.

The archaeological heritage of Iraq includes sites in the modern Republic of Iraq, which comprises Mesopotamia proper, that is, the region between the rivers Euphrates and Tigris, where much archaeological research has concentrated in the past. In addition, sites in Western Iraq, bordering Syria, and in the autonomous region of Iraqi Kurdistan (Northern Iraq) are included among those that constitute the archaeological heritage of Iraq. This heritage attests to the earliest forms of sedentary life in the Late Neolithic period, dating from the 8th to 5th millennia BCE. Younger sites are subsumed under the period of "written history" or "recorded history," the beginnings of which are marked by the development of the earliest written languages, Sumerian and Akkadian, in the 4th and 3rd millennia BCE. The period of written history gave rise to the first cities and city states, while later archaeological materials date to the Assyrian and Babylonian Empires. In addition, the archaeological heritage of Iraq also includes material remains from the Achaemenid, Seleucid, Parthian, Roman, Christian, and Sassanid periods. Today it is moreover commonly understood that sites dating later than the Arab Islamic conquest are also part of the archaeological heritage of Iraq. This refers to the time period from the seventh century CE until Iraq fell under rule of the Ottoman Empire in the sixteenth century CE.

Of the archaeological sites in Iraq, UNESCO has inscribed three major sites into the World Heritage List: Samarra Archaeological City is officially a World Heritage site since 2007, Ashur/Qal'at Sherqat since 2003, and Hatra since 1985. Ashur and Samarra are also placed on the World Heritage List in Danger. Ten archaeological sites are found on the Iraqi Tentative List for World Heritage. These are the sites of Ur, Nimrud, Wasit, and Thilkifl; the ancient city of Nineveh; the fortress of Al-Ukhaidar; the sacred complex of Babylon; Erbil citadel; Wadi Al-Salam cemetery in Najaf; and Amedy city.

The fact that the archaeological heritage of Iraq includes endangered sites bespeaks the problem of the management and protection of the archaeological heritage of Iraq, which is seriously threatened by looting and illicit trafficking in antiquities due to high levels of violent conflict since the early 1990s (Brodie et al. 2006). While the Persian Gulf War (1990–1991) caused comparatively little damage to archaeological sites and monuments in Iraq, instances of illegal trade in antiquities were documented at the time. According to Iraqi authorities, some 4,000 archaeological objects disappeared following the war in the early 1990s. In 2003, in the context of the US-led war against Iraq (the Second Gulf War), events of large-scale looting and the destruction of archaeological sites but also of museums (such as the Baghdad Museum) and libraries (such as the Iraq National Library and Archive) occurred. An increase in the illicit trading of antiquities from Iraq on a global scale was also reported. During the war, sites of archaeological heritage often served as military bases for the coalition forces (Babylon, e.g., housed the US military base "Camp Alpha"), causing substantial damage.

Receiving much attention in Western media outlets, the public and the archaeological community bemoaned the destruction of a "universal cultural heritage" in the wake of the Iraq War and the loss of cultural objects signifying what has come to be understood as "the cradle of civilization." At the same time, this sparked a scholarly debate highly critical of arguments that placed the concepts of a universal heritage and of the cradle of civilization at the center of efforts to safeguard Iraq's archaeological heritage. In response, the expression of the cradle of civilization was deconstructed as a paternalistic and colonialist trope that suggests "that these countries of the Middle East have never surpassed their early glories and that the torch of civilization has since passed to Europe" (Meskell 2005: 140). The criticism of the notion of a world cultural heritage was directed against the use of universalizing language. It was argued that this language elevated Western legal-moral categories of ownership, access, and inheritance to global values, thus ignoring local or regional understandings of cultural heritage (Bahrani 1998).

Since the official end of the Iraq War on December 18, 2011, cultural institutions such as museums and libraries in Iraq have begun to rebuild, but the situation at archaeological sites often remains problematic. Even before the official end of the war, several heritage conservation initiatives were launched, some of them specifically designed to restore and conserve damaged archaeological sites in Iraq, such as the Iraq Cultural Heritage Conservation Initiative (a cooperation between the Getty Conservation Institute, the World Monuments Fund, the Iraq Ministry of Culture, and the Iraq State Board of Antiquities and Heritage). Some of these efforts focused on fighting the illicit trade in antiquities, successfully recovering around 5,000 missing Iraqi artifacts. In addition, Iraq established a national entity responsible specifically for the surveillance and protection of archaeological sites called the Force for the Protection of Sites (FPS), which operates under the umbrella of Iraq's Ministry of the Interior. While no national tourism strategy has yet been formulated, many of the efforts directed at the protection and restoration of Iraq's archaeological heritage also target the development of the country's cultural and tourism sector. As outlined in the "UNESCO Country Programming Document for the Republic of Iraq 2011–2014," the goal is to design strategies for the management of the archaeological heritage of Iraq that are sustainable and can benefit the local community.

Ireland: Archaeological Museums

Michael Ryan
Independent Scholar, Dublin, Ireland

Brief Definition of the Topic

History

Prior to the Anglo-Irish Treaty of 1921, the whole island of Ireland was part of the United Kingdom with a single National Museum in Dublin which initially had collections of industrial and

decorative arts material, ethnographical material, and natural historical specimens. The National Museum was established by law in 1877 and was for a long time considered a branch of the South Kensington Museum in London (now the Victoria and Albert Museum) which ensured that a portion of acquisitions by the London museum were diverted to Dublin. It did not have a fully developed archaeological department until the transfer to it in 1891, under certain conditions, of the Museum of the Royal Irish Academy (founded 1785) with an archaeological collection of considerable size and value built up by the voluntary efforts of the academicians with the occasional support and intervention of government. The Academy's collection had been in formation almost since its foundation and it had managed to acquire many of the finds made in major drainage projects and railway building. Creating an enviable collection of organic materials, mostly bog finds and funerary pottery, and spectacular collections of prehistoric bronze weapons and utensils, gold ornaments and early-medieval personal ornaments, and religious objects, the Academy's collection was remarkable for its depth and comprehensiveness. In 1851, the Academy was granted the privilege in Ireland of administering the ancient crown right of Treasure Trove. In 1857, parts of a notable catalogue of the collection organized on Linnaean lines and written by William Wilde were published. The transfer of 1891 gave the new National Museum of Ireland a ready-made archaeological department with an internationally famous collection. In the 1920s, the importance of the archaeological collections to a sense of national identity was recognized, and the collection was given greater prominence in public display. Thereafter, all Directors of the National Museum to date have been archaeologists or closely associated with archaeology.

After independence of the greater part of the island in 1921, the National Museum continued to collect throughout Ireland. In 1930, the National Monuments Act regulated archaeological activity in the state and gave statutory responsibilities to the museum which continue in force with a significant strengthening in the 1990s to extend its rights to claim all archaeological objects found in the jurisdiction. The collections in the National Museum allow it to maintain object-rich exhibitions of Irish prehistory and history. In addition to Irish material, it has modest classical and Egyptian collections and superb early ethnographical collections especially from the Pacific and Africa, the latter not generally on display. In recent years development-led excavation has produced an enormous volume of archaeological material which will be housed principally in the National Museum.

Key Issues: Centralization

The new Irish state was highly centralized and continues in many respects to be so. The overwhelming majority of all archaeological finds are controlled by it. As a result, local professional museums were slow to develop, one in the 1940s and another in the 1970s but with increasing frequency in the 1980s and 1990s. However, with rare exceptions, these museums' archaeological displays contain only modest selections of artifacts lent by the National Museum. Museums with significant autonomous holdings include the Cork Public Museum and the Galway City Museum. The independent Hunt Museum, Limerick, has a noteworthy, originally private, collection of archaeological material. The Waterford Museum contains substantial amounts of material from the Viking and Medieval strata of the city which it holds and manages by arrangement with the National Museum and displays elegantly. The question of overcentralization in such a small country has never been properly addressed, and fundamental issues of access are raised by that centralization. In addition, the centralization of all archaeological material poses a challenge to the National Museum which may prove to be an unsustainable burden.

Current Challenges

Among the challenges facing the National Museum and other Irish museums is declining government support since the economic and fiscal crisis of 2009. Staff shortages and the threat of deferred maintenance jeopardize major programs of registration. Investment in a major new storage and study facility for archaeological finds and

collections will require continuing support. In addition the respective remits of the monuments service and the National Museum overlap in ways unintended by legislation, and clarity of roles and spheres of activity is urgently needed. The failure to realize the potential of the ethnographical collections is disappointing. However, despite the adverse economic circumstances, museum professionals are developing public services and maintaining a notable profile in archaeological research and publication.

Ireland: Managing Archaeology on Infrastructural Developments

Rónán Swan
Archaeology and Heritage, Transport Infrastructure Ireland, Dublin, Ireland

Introduction

Ireland has an incredibly rich archaeological heritage, with more than 150,000 known archaeological monuments recorded across the country. Infrastructural developments such as motorways, national roads, and light-rail have, however, revealed an equally rich heritage of previously unknown archaeological sites. This entry highlights the opportunity presented by infrastructural development for archaeological discovery.

Definition

Transport Infrastructure Ireland (TII) was created in August 2015 following the merger of the National Roads Authority (NRA) and the Railway Procurement Agency (RPA), which, respectively, had responsibility for national roads and light-rail (including trams and metro services). With regard to archaeology and heritage, TII seeks to manage and minimize the impact of its schemes on archaeology in the context of risk management, legislative and regulatory compliance, and ensuring that public trust and value is achieved.

Key Issues/Current Debates/Future Directions/Examples

Through the course of the 2000s, Ireland developed a collaborative and partnership approach to managing and minimizing the impact of major development on the archaeological resource; this is exemplified by the **codes of practice** which were introduced for national roads in 2000 and light-rail in 2007, along with codes for other areas involving large-scale developments such as the concrete industry in 2009. These codes created a framework based on a set agreed principles and actions between the two parties (namely, the Heritage Minister and the Developer).

An important consequence of the original codes for both the NRA and the RPA was the appointment of in-house Project Archaeologists to the project design teams. This allowed for archaeological issues to be managed and addressed throughout the development process from conception to completion. Another important aspect of the codes was the emphasis on completing archaeological works in advance of the main construction.

In 2017 a new Code of Practice (Fig. 1) for archaeology was published between the Minister for Arts, Heritage, Regional, Rural and Gaeltacht affairs and TII (Department of Arts, Heritage, Regional, Rural and Gaeltacht Affairs, 2017). This amalgamated and updated the previously agreed NRA and RPA codes of practice. As with the other codes, it contains agreed principles and

Ireland: Managing Archaeology on Infrastructural Developments, Fig. 1 Code of Practice for Archaeology agreed between the Minister and TII (Department of Arts, Heritage, Regional, Rural and Gaeltacht Affairs, 2017)

actions for both parties. Significant revisions were as follows:

- The code applies to all TII-funded projects with an archaeological component, and, in addition to national road and light-rail projects, it also applies to motorway service areas, pavement and safety schemes, cycleways, and bridge rehabilitation schemes.
- An archaeological strategy is to be published, where advance works are not feasible (e.g., in urban contexts).
- There is an explicit commitment to publish and disseminate the archaeological results of TII projects.

The Royal Irish Academy's *Archaeology 2025: Strategic Pathways for Archaeology in Ireland* (2017, pp. 31) noted that codes of practice have "been welcomed across the sector as encouraging greater consistency" and goes on to highlight that their introduction has:

- "seen project archaeologists develop contracts for the engagement of archaeological consultants to carry out archaeological works in accordance with specifications and standards
- led to a streamlining of the development process, with significant improvement in the speed and efficiency of archaeological mitigation, resulting in time and cost savings
- led to the development of new standards and practices
- seen a significant increase in the level of archaeological reporting – e.g., on national roads 96% of all reports from 2001 to 2016 have been completed and submitted to the statutory authorities, and are publicly available
- led to significant publication, dissemination and engagement programs – e.g., TII has published more than 30 books to date."

TII has developed a comprehensive suite of guidelines for the assessment of archaeology. Furthermore, TII has commissioned empirical research into archaeo-geophysical surveying and palaeo-environmental sampling which directly informs practice and methodologies and is embedded in TII's suite of contract documents. These are available at www.tiipublications.ie.This website provides the necessary standards and guidelines for undertaking TII projects, and key archaeological milestones are set out in the TII Project Management Guidelines (http://www.tiipublications.ie/library/PE-PMG-02041-01.pdf, accessed 8th October 2017).

Figure 2 illustrates TII's standard approach to archaeological works. Firstly, a route is assessed

Ireland: Managing Archaeology on Infrastructural Developments, Fig. 2 TII approach to archaeological works

through archaeo-geophysical surveying or LiDAR during the preliminary design. Then archaeological teams are engaged to carry out comprehensive archaeological test excavations; typically 12.5% of the route is investigated across the route (stage I). Then at stage II, the nature, extent, and characteristics of the archaeological sites are exposed. These are fully excavated at stage III. At stage IV samples and artifacts are analyzed, the final report is produced, and the archaeological results are published and disseminated. In turn, these results will help inform future projects and schemes.

It has always been a cornerstone of TII policy to inform the public of the results of its archaeological works, and a multilayered approach is adopted to achieve this. This strategy is exemplified by TII's annual program of events to mark Ireland's Heritage Week, which coincides with the European annual Day of Heritage. Site tours, public lectures, pop-up exhibitions, and seminars are held throughout Ireland to showcase archaeological works taking place on TII schemes across the country. In 2017, more than 1,500 people participated in one or more of these events.

Perhaps the most significant dissemination initiative has been the establishment of the TII Digital Heritage Collections (Fig. 3) in partnership with the Discovery Programme and the Digital Repository of Ireland (DRI), which has seen the uploading of archaeological reports from TII (including NRA and RPA) projects into the DRI.

Ireland: Managing Archaeology on Infrastructural Developments, Fig. 3 TII Digital Heritage Collections

In addition to archaeological reports, short videos, audiobooks, and papers from the NRA seminar series are all securely stored and digitally preserved in the DRI and are also accessible from the Irish government's open data portal (https://data.gov.ie/) and the Heritage Council's web-based spatial data viewer (https://www.heritagemaps.ie/). In due course other digital outputs will be added to these collections, including laser scans, archaeo-geophysical reports, drone footage, etc. (Fig. 4).

TII is one of the most significant commissioners of archaeological work in Ireland and, given its national remit, is perhaps uniquely placed to contribute to the understanding of Ireland's past. Since the early 2000s, more than 2,500 archaeological sites have been excavated across the island. In the course of these works, many significant sites have been excavated and have been fully published (e.g., the recent volume *Meitheal* on Raystown, Co. Meath, describing an early medieval farming settlement and milling center, and the volume on the medieval village at Mullamast, Co. Kildare). TII's recent volume, *Stories of Ireland's Past*, presents a critical synthesis of archaeological discoveries made since the establishment of the NRA (Stanley et al. 2017).

One of the most important outcomes of TII's approach is that it unequivocally demonstrates the ubiquity of archaeological sites throughout the Irish landscape (Fig. 5). For academics and researchers, it requires them to fundamentally reassess their assumptions and models of past settlement and activity, while planners and developers need to assume that new archaeological sites will nearly always be discovered in the course of works and plan accordingly.

Irish Post-Medieval Archaeology Group (IPMAG)

Audrey Horning
Queen's University Belfast, Belfast, Northern Ireland, UK

Basic Information

The Irish Post-Medieval Archaeology Group (IPMAG) was formed in 1999 and is a cross-border organization dedicated to fostering interest in the archaeology of Ireland from the period 1550 to the present. The stated aims of the group include undertaking initiatives that will help raise the profile of post-medieval archaeology

within (and beyond) Ireland; fostering greater contacts between those individuals engaged in researching the archaeology, history, and culture of post-1550 Ireland; and lobbying for increased academic attention to be paid to the post-medieval period in Irish universities. The group held its first conference in Belfast in February 2001, and annual conferences have followed each year, at venues throughout the island of Ireland. The group publishes an ad hoc newsletter, maintains a web site with a range of resources relating to historical archaeology in Ireland (http://www.science.ulster.ac.uk/crg/ipmag/), and has an active program of publishing its conferences as monographs. IPMAG has also been proactive in lobbying respective governments in relation to adequate protection for post-medieval sites, landscapes, and materials. Yearly field trips are also organized by the group to explore post-medieval sites and landscapes in Ireland, north and south. The membership is international in composition.

Major Impact

Prior to the establishment of IPMAG, there was little organized support for historical archaeology within Ireland, north and south. The contested nature of Ireland's early modern and modern history, in relation to the extension of British control over the island, had long dampened interest in the period as being worthy of archaeological attention. The establishment of the group therefore provided a forum for those interested in the period and legitimacy for the subject. Now, all of the major universities on the island teach some form of historical archaeology, and the number of postgraduates pursuing related research continues to increase each year. IPMAG has also played a central role in encouraging the broader reach of Irish historical archaeology through the publication of four major monographs *The Post-Medieval Archaeology ofIreland, 1550–1850* (2007); *Plantation Ireland* (2009, with the Group for the Study of Historic Irish Settlement); *Ireland and Britain inthe Atlantic World* (2009, with the Society for Post-Medieval Archaeology); and *Crossing Paths, Sharing Tracks*, *Future Directions in theArchaeological Study of Post-1550Britain and Ireland* (2009 with the Society for Post-Medieval Archaeology and the Association for Industrial Archaeology).

Introduction

The study of ancient iron smelting in Africa has been, in recent decades, the center of interest of

many researchers in archaeology, history, anthropology, and so on. The stake and the interest of this study is the knowledge of the history of techniques in West Africa in which the approach of ancient metallurgy of iron is inscribed. At the very beginning of these investigations, the origins of technology were most often discussed. At the current state of research, the scientific debate is no longer at the level of the origins of this metallurgy especially as it has sparked publications that have finally confirmed the autochthony and the age of this industry in Africa, which probably did not know that a single center of origin and diffusion: 1000 BC in Niger, site of Termit; 800 BC in Nigeria, Jos region; 1000 BC in Central Republic of Africa; and 1200 BC near the Victoria Lakes (Bocoum 2002: 61; Robion-Brunner 2018b).

Scientific research carried out in recent decades on the ancient iron metallurgy has often emphasized technical, human, and sociocultural aspects. These revealed knowledge at the level of science, knowledge and know-how, technologies, myths, cosmogony, etc. which show a wealth and an undeniable material and intangible heritage.

The ancient metallurgy of iron, as practiced in Africa until the middle of the twentieth century, is a set of technical processes for obtaining iron from ore, by smelting of oxides. These processes are part of the operating chain. The latter consists of several stages that range from prospecting, the collection or extraction of iron ore, the preparation, and the smelting of iron ore in the furnaces to the transformation of the magnifying glass into finished products in the forge. This operating chain is rich in the technological specificities of each metallurgy, which leads to a diversity and an exceptional wealth of practices. However, contact with the West, colonization and the introduction of iron bars, and iron recovery in West African societies will lead to real changes in the production of iron, especially in the region. Forge, where technical and cultic practices continue today in our societies south of the Sahara.

In this approach we present the technical and cultural richness of this iron technology known largely thanks to the ethnographic investigations, to the vestiges and sites of this industry discovered all over West Africa, and to the adaptation of the techniques of the blacksmiths the demands of the modern world, which is driving a real technological change.

The Ancient Metallurgy of Iron in West Africa: A Wealth of Innovative Processes

Apart from archaeological research, much of the knowledge of the technical and sociocultural aspects of the operating chain of early iron production is known through ethnographic and experimental investigations. Indeed, these deliver results that complete the data of archaeology, thus allowing the understanding of the metallurgical activity, abandoned more than half a century ago.

Traditional iron metallurgy has several stages. At each of them, ritual and forbidden techniques are omnipresent and mark the inseparable character between material technical aspects and immaterial ritual aspects.

From the Mine to the Smelting of Iron Ore

All operations to obtain the bloom include prospecting, collecting where ore extraction, iron ore preparation, furnace construction and reduction of ore in furnaces.

Ore Prospecting or Prospecting

In Africa, prospecting methods are varied and very diverse depending on the time, space, and prospecting period. The operation of prospecting or finding the ore is most often the responsibility of the most experienced men with a ritual knowledge to complete the stage. During the prospection, divination practices often precede the operation. In particular, Gulmanceba metallurgists in Burkina Faso practiced geomancy to determine if the output would be successful by determining the directions to be taken for prospecting, the favorable moments, and the sacrifices to be made before the prospection campaign (Thiombiano-Ilboudo 2010: 249).

In addition, several indices based on very old knowledge can locate the iron ore. In fact, the knowledge of nature and the observation of certain plants are determining factors that make it possible to locate the iron ore during the

prospection. The presence of certain plants such as *wiliwiga* (*Guiera senegalensis*), *wędga* (*Saba senegalensis*), and *kubrsak* (*Cassia sieberiana*) reveals the existence of iron ore under certain formations of ferruginous cuirass (Kiénon-Kaboré 1998: 87). In the Moosé of central, northern, and northern central Burkina Faso, the observation of the smoke emanations released from the ground after the rain or in the evening after falling temperatures was a sign of the existence of the ore. The prospecting techniques are indeed diverse and denote the wealth of these metallurgies of iron in West Africa which are not exhaustive in this study.

Obtaining Iron Ore

The techniques of obtaining the ore are various, and most often it is about collection of surface, open excavations, trenches, and wells (of circular or rectangular form some of which with galleries). In Africa in general, extraction by circular or rectangular well is one of the most common extraction methods.

At this stage of the operating chain, rituals are still ubiquitous. Minors must abide by certain rules, such as not having sex the day before the operation or with the same women before the start of the extraction. The exploitation of iron is surrounded by a large number of rites and taboos, so as not to offend the living spirit of the iron on which depends the smooth running of operations (Kiénon-Kaboré 2003). Prohibitions related to the extraction of ore are a means to secure the production of iron by establishing a climate of peace and social harmony between blacksmiths to avoid any social tear that could be fatal to the duties assigned to them (Kienon-Kaboré 2017).

The work in mining operations is very difficult and therefore requires a large workforce. To extract iron ore, miners use several types of equipment such as picks with extremely rigid blades, daba, traditional flashlights to illuminate the interior of wells, baskets and ropes to raise the ore, etc. The work was done at the chain. The persons in charge of the extraction and the transport are generally men; however in some societies as among the Gulmanceba, the women took part in the works. The extraction periods were those of the dry season, between January and April, so as not to be hampered by rainwater. This period allowed the blacksmiths to take advantage of the season free of field work to make the material and not lose an annual campaign of culture, for those who were metalworkers and farmers. The search for the ore was a decisive step, but the preparation of the latter before its introduction into the furnace conditioned the success of the operation.

Ore Preparation

Regarding ore processing, metallurgists used several processes. These include crushing, sizing, washing, drying, and roasting. All these treatment techniques can be grouped into two types, namely, physical and thermal treatments. Physical treatments include sight sorting, crushing, sizing, and washing (Robion-Brunner 2008: 205). They make it possible to reject the iron-poor parts and to improve the behavior of the ore during the smelting process.

In the Moosé and Gulmanceba of Burkina Faso, and the metallurgists of Benin, the ore was either simply crushed and calibrated in small pieces the size of a chicken egg by experienced people, or it underwent other treatments that allowed to modify the nature of the ore to facilitate smelting (Kienon-Kaboré 2003: 102). On the other hand, at the Senufo of Koni, in the north of Côte d'Ivoire, at the extraction of the ore, they obtained a powder that had first to be moistened, shaped into small balls the size of an egg hen, which was then allowed to dry before loading into the furnace (Kiethéga 1996: 311). Some ores were washed to rid them of clay loam that could hinder the smelting of iron ore and reduced to powder and then to an egg-sized ball (Essomba 1983).

Heat treatments – roasting, for example – are the firing of an ore in an oxidizing atmosphere and at temperatures well below the melting point (800–900°). This operation allows dehydration (disappearance of water molecules), decarbonation (transformation of carbonates into oxides by release of CO_2), or desulfurization (release of sulfur contained in sulfides) of the ore (Robion-Brunner 2008: 205). It is noted that all these treatment techniques serve a specific purpose, facilitating smelting while achieving good yields.

Furnace Construction

Before the smelting, the furnace construction is of paramount importance. However, it is important to note that given the diversity of furnaces in West Africa, it would be imperative to take them all up with the stages of their construction. We will discuss the construction of a simple and well-known furnace type that encompasses the wealth of knowledge in the field. The furnace and accessory construction techniques are diverse and result from the multitude of techniques employed in African societies. There are furnaces with natural draft or forced draft or furnaces underground, semiunderground, open-pit, pit, etc. In this approach we present the example of the forced air draft furnace which also shows the technical richness of these metallurgists. Water, clay, and straw are the essential materials. The termite mound soil is also used for the construction of the furnace because of its better soil quality which, according to the metallurgists, withstands the high temperatures of smelting. The clay is kneaded with straw which is allowed to rest for several hours. Meanwhile, a bundle of millet stems made and cut to the size of the future furnace is attached in three places to have the frustoconical shape of the future furnace. Then, the metallurgist clears the ground and digs a circular pit (about 20 cm deep) to the shape of the base of the furnace (about 1 m in diameter), in the center of which it makes a hole. He arranges for the pit to have an inclined slope on the west side. After that, the bundle of millet stalk is transferred there and serves as a mold for the construction of the furnace. The kneaded clay is placed all around it and plastered with a corncob, fingers, and other suitable equipment. Three days later, the bundle of millet stalk is removed or burned inside the furnace that has taken shape. This last operation has a double advantage. The heat helps to harden the furnace, and the resulting ash, which remains in the crucible, allows the magnifying glass not to weld to the ground.

The construction of the furnace is followed immediately by the realization of the accessories. The manufacture of pots and secondary nozzles obeys the same principles as the furnace, with the difference that the latter two do not use the same molds. For pots of the blower, a terrine of about 30 cm in diameter is essential. The mold of the secondary nozzles is a cylindrical wood 1 m long and about 14 cm in diameter. The main nozzle has the shape of a funnel and serves as the junction point of the two secondary nozzles, at the opening of the furnace, where it fits first. It plays the role of air duct here; otherwise the air could disperse at the junction of the two secondary nozzles. A forked wood is used to keep the furnace tilted.

With the furnace construction completed, the blacksmith prepares for the smelting stage. The basic elements are the ore, the fuel, and the oxidizer (air) essential for the rest of the operation.

Combustible

A variety of fuel was used for the smelting of the ore, and each had specific qualities that acted on the good smelting of the ore. The most sought-after species were those with a high calorific value and also exhibited crush resistance in order to descend without crumbling or settling, a condition for the regularity of good combustion.

The choice of species is determined by the qualities specific to the species. Metallurgists have most often used green charcoal because it has a higher heating value than dry wood. In Burkina Faso, in the province of Bulkiemdé, metallurgists most often use *Khaya senegalensis*, *Guiera senegalensis*, *Detarium microcarpum*, *Burkea africana*, *Cassia sieberiana*, *Terminalia macroptera*, and *Butyrospermum parkii.*

Burkea africana, *Detarium microcarpum*, and *Terminalia macroptera* are much more commonly used in blacksmithing. One mentioned has the reputation of making the iron easy to handle the purification and gives a very good quality to the metal. *Khaya senegalensis*, *Guiera senegalensis*, *Burkea africana*, and *Cassia sieberiana* are used for both smelting and forging. In the majority of blacksmiths, *Cassia sieberiana*, the roots of *Guiera senegalensis*, and the *Khaya senegalensis* carbonized together facilitate the smelting of iron ore. The *Burkea africana*, considered as the best in forge and the furnace, is the

species most sought after by all blacksmiths of Bulkiemdé (Kiénon-Kaboré 2003).

The Smelting of Iron Ore

This stage also begins with sacrifices and rituals that differ from one society to another. The mode of loading depends on the blacksmith and the type of furnace. Sometimes ore and charcoal are alternately laden, as is the case in some Moosé, Gulmanceba, Bwa, and Dagara populations of Burkina Faso, Bassars of Togo, Niger, and Ivory Coast. Some metallurgists dispose of the charcoal in the middle of the furnace after making a crucible, and then the ore is put all around it.

The forced air draft furnace by the use of bellows works most often in the morning (5 am–18 pm). This type of operation allows metallurgists to have control over the intensity of the air. They may decide to stop, increase, or slow down the supply of air depending on the progress of the operation.

On the other hand, most natural air draft furnaces work at night. These are the case of the furnaces of Yatenga and some of Niger. The smelting takes place every night between 6 pm and 5 am; the smelting operation takes into account the wind conditions. Indeed, the absence or excess of air can affect the operation of the furnace by smothering or very rapid combustion of coal. This reason may have guided the blacksmiths to run the natural air draft furnaces at night, where the winds are moderated in some parts of Africa, to avoid malfunctioning.

The magnifying glass obtained after the smelting can be used directly in the forge for the manufacture of finished products or undergo purification at the smelting sites to facilitate refining at the forge.

The knowledge of the operational chain of the old iron metallurgy through ethnographic data shows the wealth of this traditional industry which includes geological, technical, mineral, chemical, meteorological, etc. They contain values of all kinds that disappear over time and the modernization of different African societies.

The work of the forge is also an important step which also includes technical and cultural knowledge and know-how.

Forging the Object

This phase is the transformation of the metal into a finite object. The blacksmith has a wide range of gestures and technical processes determined according to his raw material, his skills, his knowledge, the complexity of the object to be manufactured, and economic constraints (Robion-Brunner 2008: 216).

The Workshop of Forge

In the forge workshops, the magnifying glass obtained by the metallurgists was intended for the manufacture of tools for field work, weapons of war, and domestic, cultural, and religious objects. The workshop had a variable layout, workshop tools were diverse, and staff depended on the origin of blacksmith. The blacksmith's workshop at Bulkiemdé in Burkina Faso has a small forge of reduced size. It consists of a conical thatched roof shed. Circular in shape, it measures approximately 3 m in diameter and is composed of bellows, which are always two in number, with a fireplace and an anvil. Bellows are constructed in the same way as those of furnaces, with the only difference being that forges are small (Kiénon-Kaboré 2003). The same type of development is found in the Gulmanceba blacksmiths of Fada N'Gourma in eastern Burkina Faso where the roof is covered with a roof of millet stalks (Ilboudo-Thiombiano 1991). The spatial organization of the forge respects a certain number of prohibitions and mystical facts. The forge workshop can be family or community and most often located outside the family yard, in the center of the village.

Forging Equipment

The blacksmith uses specific tools for making finished products in the forge. These elements are most often common to African forges. The forge material is composite. We have iron anvils fixed on a tree trunk, chisels (for cutting), limes (for sharpening), pliers (to seize the red iron), hammers (for pinging), buckets, and cans. The anvil is the central element of the forge given its technical and cult role. It is a frustoconical mass of variable size, embedded in a tree trunk or inserted

directly on the ground. Some companies use a mass of stone. At the level of the blacksmiths of Bulkiemdé, when the blacksmith decides to stop his trade, it remains the only element of the forge implanted to serve for ritual ceremonies of care or protection. Aside from the anvil, master piece of the forge, there are other types of tools each having a specific function. The pincer is the most used among these secondary tools. It is used to introduce, remove the heated object from the fireplace, and soak the iron in water. The chisel often has two different dimensions (a smaller one to cut small pieces of iron and the largest to cut larger blocks) serves, using the pincers and the hammer, to cut the supports of objects to make up. The needle is used to drill holes in tools that require them. To polish the sharp parts of knives, blades, and lances, the blacksmith uses a kind of scraper.

The blacksmith uses fabrication techniques that start with hammering, dipping, welding, and other techniques of recoiling and chemical surface treatment for some delicate objects such as blades, lighters, knives, etc. (Kiénon-Kaboré 2003).

The Products of the Forge

With this forging material, the blacksmith manufactures tools, the majority of which consists of instruments for domestic use such as ladles and spatulas. The tooling for field work, such as the axe, the ermine, and the la, is the most requested and most made by the blacksmith. Apart from these indispensable items for farmers, the artisan blacksmith also manufactures small domestic materials such as large needles used to make holes on the damaged parts of the wooden gourds in order to repair them. The tools of decoration of the leather, the iron for spinning cotton, and the making of mats are also the fact of blacksmiths. Other objects such as rings, amulets, and bracelets that serve to protect themselves from diseases and evil spirits are also the work of blacksmiths. Artisans use techniques of making objects that denote technical know-how and wealth. Each object has its own approach specificity that highlights a certain subtlety.

The forge in African societies has extensive functions. It is used not only to make the necessary tools for society but also plays an important cultural and worship role.

The remains of all this inheritance are most often remnants of iron metallurgy and are composed of extraction wells, heaps of slag, furnaces of smelting, etc.

Sites of the Ancient Metallurgy of Iron: A Technological Diversity in West Africa

The witnesses to this technical heritage, which show the former importance of iron metallurgy in these societies in the south of the Sahara, are most often found in rural areas. The remains and sites at the level of urban areas are most often destroyed by rampant urbanization. A large part of the whole of this technical heritage is currently in ruins for natural and anthropogenic reasons. These are diversity of sites and archaeological remains reminiscent of a recent past very active in the production and marketing of iron metal. In this article, we have chosen to present only few examples of metallurgical sites in West Africa in order to show the technical and heritage wealth of this industry. Each country of this part of Africa has benefited from more or less extensive research that has revealed many iron production sites, but we will only present those in Benin, Burkina Faso, Côte d'Ivoire, Mali, and Togo. The research presented for each country mentioned above is not exhaustive.

Benin

Research on ancient iron metallurgy in this country has made it possible to chronologically date the beginning of iron metallurgy during the first millennium BC in the Mono region (Randsbord and Merkyte 2009). During the first millennium AD, the iron production is becoming more widespread. Iron is produced in the Atakora from the fifth century AD (Ndah 2009: 435), in the Dendi Region from the fifth century AD (Robion-Brunner 2018a), and in the northeast of Benin, in Boo country, from the twelfth century (Banni-Guénné 2012).

In the Atakora region, metallurgical sites of ancient iron have been identified in the Tanguiéta region, Boukombé, Koukouabirigou, Koutacoingou, and Tèkouantè, and in the Natitingou region, Perma,

Bouyagnidi, and south of Tayakou at the edge of the waterway called Ouankou. At Kèténkè, a site was located 10 km east of the village. It is composed of a large furnace of the Boonga type of central and northern Burkina Faso. It can reach a height of 3,75 m with a circumference of nearly 4, 30 m.

In northeastern Benin, research has highlighted several iron metallurgical sites (Banni-Guénné 2013). On the smelting sites of Ségbana, Kaiama, and Bensékou, Oumarou Banni Guene identifies two types of processes which he calls process Munga and Fufuna which are, respectively, the fact of sedentary and itinerant blacksmiths in the Borgou in Boo country. The Fufuna furnaces are smaller compared to those of the larger Munga process (Photo 1).

In the Dendi country, five smelting traditions divided into three groups have been distinguished: that of the reusable furnace with tapped slag (tradition 1), that of the non-reusable furnace with internal slag (tradition 2), and finally those of the reusable furnace with internal slag (traditions 3–5; Fig. 1; Robion-Brunner 2018a). The localization of iron traditions shows that the northwest is more diverse than the southeast. All the traditions are present around the village of Pekinga. This area seems to have welcomed blacksmiths belonging to diverse geographical origins. The craftsmen expressed their identity through their skills. We still do not know whether their settlement was contemporary, but what is certain is that Pekinga was a crossing zone. A series of 12 radiocarbon dates and oral traditions confirm that iron production started at least at the end of the first millennium AD and progressively decreased since the beginning of the twentieth century. Data are currently insufficient to assess the beginnings and fluctuations in iron production over this long period and to conclude whether the different traditions were contemporary or consecutive. Nevertheless, the variability of the metallurgical remains probably reflects significant modifications in population settlements. Moreover, some of these variations are very close to other West African remains. At least four traditions have the same spatial organization, the same type of furnace, and the same type of slag as those observed at Korsimoro by Serneels (Serneels et al. 2012, 2014) and near Niamey by Guillon (Guillon et al. 2016).

Iron Ironworks of West Africa, Photo 1 Furnace Munga. (Photo Banni-Guéné 2013)

More than 30 iron smelting sites have been located on the Abomey-Bohicon plateau and around the cities of Dogbo and Kétou (Fig. 2). Their activity began timidly during the first millennium BC and expanded from the second half of the first millennium AD east of Sodohomé. At its peak around the fifteenth century, it stopped abruptly at the beginning of the sixteenth century before the establishment of the kingdom of Dahomey. However, during this reign (1650–1900), iron objects were manufactured locally, but from iron imported either from neighboring regions or from European countries (Burton 1864). One of the possible reasons given for the end of iron production in the Mono is the arrival in the middle of the sixteenth century of an episode of drought in this region already subject to the effects of Dahomey Gap. This climatic factor in a dry subhumid environment makes biomass regeneration problematic and thus the availability of wood and therefore coal, an essential fuel for operating reduction furnaces and forging furnaces (Randsbord and Merkyte 2009). The study of

Iron Ironworks of West Africa, Fig. 1 Localization of the five smelting traditions in the Dendi country

archaeological remains and iron production volume showed the existence of three periods corresponding to different production levels and techniques (Randsborg and Merkyte 2009: Fig. 2):

1. Between the eleventh and twelfth centuries AD, iron was produced between Tado and Sodohomé in small bellows furnaces.
2. Between the thirteenth and fourteenth centuries, the furnaces operated with natural ventilation distributed in the tank by several small tuyères, the smelting workshops established outside the housing areas multiplied and occupied a wider region ranging from Cheito in the west to Kétou in the northeast and Pobé in the southeast, and their production met a wider regional demand, probably including long-distance trade.
3. Between the fifteenth and sixteenth centuries, the furnaces, still naturally ventilated, were now equipped with several large tuyères. Real pre-industrial districts are being set up, but refocused on the southwestern part of the area. Their production, in excess, is then turned toward an export extra-regional. Through topographical surveys and cubages, it is established that the latter have produced more than 60,000 tons of slag over six centuries (Randsborg and Merkyte 2009).

Iron Ironworks of West Africa, Fig. 2 The iron smelting sites of the Mono region with different chronological periods and different types of nozzles. (According to Randsborg 2009: 211)

As this estimate does not take into account all reduction workshops (calculations are based on data from 12 smelting sites out of the 30 identified), iron production was expected to be even higher, placing the Mono region on the list of the most important iron centers in West Africa.

The dimensions of the tuyères and their number are directly related to the morphology of the smelting structure. Sometimes markers of the ethnic origin of metallurgists, these elements often materialize population movements in a region. Crossed with ethnohistorical data, the analysis of archaeological remains makes it possible to trace the history of the iron industry and blacksmiths (Randsborg and Merkyte 2009). Thus, the large tuyère furnaces set up in the fifteenth century are associated with the arrival of Gbe-speaking peoples in the Mono. Gradually driving the Yoruba people to the East, who used to use small nozzles, these new populations bring a technique that seems more efficient, allowing the increase in iron production.

Burkina Faso

Burkina Faso, like other sub-Saharan African countries, has been a major iron-producing area over the past centuries. The importance of this industry is perceptible through the sites and

vestiges discovered throughout the territory. Some metallurgical sites have brought decisive data to the understanding of the history of ancient iron metallurgy in Burkina Faso. We can cite those of Ronguin, Tiwêga, Kindbo, Yamané, Korsimoro, Wolgteng-gooden, Tougaré, Beli in the Markoye region, etc.

Research in recent years has made it possible to advance a little more in the understanding of iron metallurgy in Burkina Faso. Among these investigations, those of Yamané-Nimpoui and Korsimoro have made it possible to renew the knowledge of ancient iron metallurgy in Burkina Faso.

The site of Yamané-Nimpoui is located 70 Km north of Ouagadougou. It houses numerous remnants of iron metallurgy composed of iron slag, nozzles, furnace walls, and well-preserved furnaces. The excavations made it possible to identify a first type of furnace which measures about 3, 5 m high and a second type whose bases are very eroded. One of the main characteristics of the first type of furnace is the presence of a cylindrical block in the center of the furnace during the smelting that works with a natural draft. The coal collected during the excavations made it possible to date one of the structures by 14c dating in the fourteenth century AD (Serneels et al. 2015: 4).

Another important site was identified and excavated at 70 km northeast of Ouagadougou. It is the metallurgical site of the iron of Korsimoro. In this region there are several technical traditions, the first identified of which present certain peculiarities (Serneels et al. 2011: 23–54). The first is the set of large, single-use slag furnaces. These are circular furnaces aligned on a straight line that worked with battery (Photo 2). The dates obtained are between the seventh and tenth centuries AD. The second type is characterized by large reusable, trapped slag furnaces that provide dates between the eleventh and thirteenth centuries AD. The furnaces are massive buildings scattered with natural draft of air. They have four openings, and the cylindrical and massive nozzles (diameter 12–15 Cm) are reused. Technical tradition 3 consists of large, reusable, cast slag furnaces dated between the fourteenth and sixteenth centuries with a single furnace placed in the center of an elliptical work area. The releases form a ring with a slag mound placed in the west. The nozzles are relatively small, 3–4 cm in internal diameter and 7–9 cm in outer diameter, and the slags found are blocks of cast slag. The furnace sometimes has five openings. As for technical tradition 4, it is represented by small, single-use, trapped slag

Iron Ironworks of West Africa, Photo 2 Technical tradition KRS1 (Photo Serneels et al. 2011)

Iron Ironworks of West Africa, Photo 3 Technical tradition KRS4 (Serneels et al. 2013)

Iron Ironworks of West Africa, Photo 4 Furnace tradition KAN1 in Siola (Serneels et al. 2013)

furnaces dating from the seventeenth century. The furnace bases are of very low diameter which contains a massive cylindrical slag. They are presented by battery of 10–50 units. The diameter varies between 15 and 25 cm, and the depth is 30–40 cm and reaches exceptionally 80 cm. The use of bellows is most likely for its operation (Photo 3).

The diversity of archaeological data and technical traditions on ancient iron metallurgy in Burkina Faso shows the dynamism of this industry over the past centuries. Burkina Faso, in view of these research results, constitutes an important center of production which the ethnographic data also confirms.

Ivory Coast

In Ivory Coast, the results of excavations in the Folon region of Kaniasso in the northwest of the country have provided important scientific knowledge on the production of ancient iron metallurgy. Metallurgical technical traditions are identified, and the first absolute chronology on this theme is obtained for the first time in Côte d'Ivoire. Different technical traditions are identified from the earliest investigations in the village of Siola, KAN 1 (eleventh to fifteenth centuries AD), KAN 2 (fifteenth to twelfth centuries AD), and KAN 3 (seventeenth to nineteenth centuries) (Serneel vincent et al. 2013).

The first technical tradition KAN 1 (eleventh to fifteenth centuries AD) located in area 2000 of

Iron Ironworks of West Africa, Photo 5 Furnace tradition KAN 1 in Doumbala (Serneels et al. 2015)

Siola and Doumbala-Kokoroni K-301 is the set of furnaces constructed of sunken slag nozzles. It is characterized by the presence of small elliptical or subcircular mounds consisting of small fragments of slag cast in cords. The nozzles associated with the KAN 1 tradition are cylindrical and small gauge. They are reused for the construction of the furnaces (Photos 4 and 5). The furnaces are built on pillars formed by blocks of irregularly shaped laterites above; a wall constructed using

Iron Ironworks of West Africa, Photo 6 Tradition KAN 2 in Siola (Serneels et al. 2013)

Iron Ironworks of West Africa, Photo 7 Furnace tradition KAN 2 in Doumbala (Serneels et al. 2015)

cylindrical sections of used nozzles is mounted. Initially, the furnaces are installed above a low elliptical depression in the bedrock. The furnaces probably work with a natural draft fed by nozzles, and the flow of slag through the door during the operation is the rule. In spite of everything, some internal slag also forms (Serneels et al. 2013).

The second technical tradition KAN 2 (fifteenth to seventeenth centuries AD), characterized by trapped slag furnaces, is composed of broken blocks of internal slag. This KAN 2 tradition has been identified at Siola 1200–1300 and Doumbala-Kokoroni K-201. The furnaces are subcircular constructions of 1.3 m in diameter. The material is a clay mixed with some gravel. These structures are reinforced by sections of used nozzles, arranged horizontally and which are then encompassed in the Earth mass (Photos 6 and 7). These pillars are 30 cm wide and 50 cm high. Then a clay wreath connects the pillars. The furnaces have been used repeatedly, and the air supply is probably based on a natural draft, with at least six large nozzles. The slag accumulated at the bottom of the furnace is evacuated after cooling the furnace.

The third technical tradition KAN 3 (seventeenth to nineteenth centuries AD), consisting of very large furnaces with trapped slag, is characterized by large annular clusters consisting of large blocks of internal slag surrounding a

Iron Ironworks of West Africa, Photo 8 Tradition KAN 3, site of Siola (Serneels et al. 2013)

structured work area. At the center is a very large furnace with an external diameter at the base of more than 2 m. The furnaces are very powerful constructions (Photo 8). They have a door and four or five doorways. They are built to serve a lot of times. The furnaces probably work with a natural draft. The remains of the KAN 3 tradition are impressive. In half of the cases, the accumulation of slag is 2.5 m high or higher.

A fourth tradition is highlighted in Siola in area 4000 and dated from the eleventh to the thirteenth century (Serneel Vincent et al. 2015: 93). In fact, surveys have made it possible to

update furnace bases after a depth of 50–80 cm. The furnaces are clearly distinguished from the structures belonging to the other technical traditions of the Kaniasso District. These are pits dug into the lateritic bedrock. They have an elliptical shape (Photo 9) and have a well-marked door, about 60 cm wide, placed at one end of the large axis of the ellipse. This area of Siola 4000 contains remnants of nozzles specific to their shape. These are large massive nozzles longer than 40 cm, weakly tapered with a subcircular to elliptical section. The peculiarity of these nozzles is the existence, in addition to the normal nozzle, of three perpendicular openings of rectangular or circular section according to the models (Photo 10). The activity was intense, with at least 200 furnaces in operation. However the complexity of the structures does not allow at this stage the work to clearly characterize this technical tradition.

Iron Ironworks of West Africa, Photo 9 Furnace tradition KAN 4, site Siola 4000 (Serneels et al. 2016)

Mali

In Mali, many vestiges testify to the production of iron. The study of those established on the Dogon plateau revealed the existence of different techniques present in a relatively small territory and operating at the same time. The work has resulted in dates extending from the sixth to the twentieth centuries AD (Robion-Brunner 2008: 237–347). In total, six (6) technical steel traditions have been clearly identified based on the spatial organization of production sites, furnace types, and associated waste assembly.

In the Fiko tradition, furnaces are often organized in drums of two, occupying a more or less circular work area. The slag is rejected on the periphery of the smelting area and forms a frustoconical cluster whose center has a crater with almost vertical walls and reinforced by slag walls.

There are double clusters due to the junction of two clusters. The furnaces are imposing structures of elliptical plan (2.5 × 1.5 m) with a basin-shaped lower part. At mid-height, the wall of the furnaces is pierced by a series of embrasures intended for the installation of massive nozzles. The vaulted superstructure is 2.5 m above the bottom. The majority of the slags are poured, but slabs in the form of slabs are encountered. The

Iron Ironworks of West Africa, Photo 10 Nozzle with lateral opening, Siola 4000 (Serneels et al. 2013)

beginning of production on the site of Fiko remains unknown, but it is clearly attested from the year 1100 AD and continues until around 1900 (Robion-Brunner 2008).

In the Ouin tradition, a single furnace occupies the center of a cluster of annular slags. The workshops consist of one or more rings. The furnaces have a circular section of one (1) m in diameter. They have a lower pit about 50 cm deep, a door, and 5–8 embrasures with a chimney up to 1.5 m above the traffic floor. On the side, a sandstone block staircase gives access to the upper opening. The slag is poured and the tuyères massive. The lower part of the chimney was built using lozenge-shaped raw bricks. These furnaces share similarities with furnaces from Yatenga (Burkina Faso) and attributed to Kibsi metallurgists, who were present before the conquest of the country by the Nakombsé in the fifteenth century AD (Kiéthéga 2009).

In the Ama tradition, site organization and furnaces have similarities to that of the Ouin tradition. The furnaces excavated at Amabalaginna are rather small (diameter 80 cm), of circular section, with a pit dug in the substrate, a door, and only five embrasures for the nozzles at the ground level of circulation and a slightly frustoconical chimney. The slag is shaped like a thick, curved plate. The solidified slag therefore has a central vacuum of the cooling mode. A large majority of nozzles is clogged with slag.

In the Tinntam tradition, the furnace construction technique is the cladding on the outside by a cladding of sandstone blocks surrounding a slag-bound construction using clay mixed with straw. On the inner walls a layer of nozzle fragments is applied, which is then covered by a thin clay film. The furnaces include a buried pit, a door, and nine narrow embrasures at the ground level of external circulation surmounted by a massive chimney high of about 2 m. The nozzles are thin and cylindrical and the slags are small cast fragments. They are frequently contiguous two by two. The spatial organization of the sites is not always the same. The other sites of the tradition are much more modest and are characterized by furnaces arranged randomly and each surrounded by a rejection of more or less annular slags.

The Aridinyi tradition is characterized by massive furnaces built of banco-bound slag. The lower part is a shallow bowl. And the globally frustoconical chimney rises about 2 m above it. The inner tank, wide at the base, closes in dome and is extended by a much narrower duct. A door and five embrasures are made at ground level of circulation. An external staircase provides access to the upper opening. These furnaces produce mainly internal slags in the form of roughly hemispherical large blocks up to 80 cm in diameter and 40 cm thick for a weight exceeding 100 kg. The nozzles are massive. The furnaces are arranged either randomly or in parallel rows. The spaces between the furnaces serve to reject the slag blocks. The accumulation of waste forms retaining walls. This is the case where on the large site of Aridinyi, the cluster of slag forms a single massive thick more than 2 m by 100 m long traveled by narrow streets lined with high slag walls connecting places occupied by furnaces.

The sites of the Enndé tradition are most often the juxtaposition of small, low mounds or even simple debris spreading. The excavation carried out by S. Perret uncovered a buried furnace base, with an access pit and a door as well as five embrasures for the nozzles at ground level of circulation. The construction is made of banco and slag. The diameter of the tank reaches about 1 m. The slag in these furnaces has irregular block shapes with flow structures and many traces of sediment adhering to the surfaces. These are bottom slag.

This research helps to understand the development of iron production in Dogon countries in the Bandiagara region.

Togo

In Togo, several researches have identified sites of ancient iron metallurgy in the regions of Bassar, Dapaong, and Tado, allowing some to situate this activity in a chronological context and to know the operative chain of this industry.

In the Bassar region, iron production began as early as the fifth century BC and ceased in the middle of the twentieth century AD. After a chronological hiatus, this activity took off at the end of the first millennium AD (De Barros 1986). The

workshops are established along two discontinuous mountain ranges rich in iron seams. The study of the volume of iron production taking into account the chronology makes it possible to divide the history of the Bassar iron industry into five periods (from Barros 1985, 1986, 2013):

1. Between the middle of the fifth century BC and the first century AD, iron was produced and transformed into an object around the Dekpassanware site.
2. Between the end of the first millennium AD and the middle of the fourteenth century, steel sites multiplied in the region, and their production was small and supplied local needs.
3. Between the middle of the fourteenth century and the end of the sixteenth century, steel activity increased and became important.
4. Between the seventeenth century and the beginning of the nineteenth century, it reached a surplus production turned toward extra-regional exports.
5. During the nineteenth century, it continued to expand, but some intersocietal relations disrupted trade and production; the latter ceased at the beginning of the twentieth century in the eastern part (Kabu/Bassar), while around the city of Bandjéli, it was not until the 1950s that local iron was permanently replaced by European imports.

Thanks to topographical surveys and cubages, production can be estimated at more than 200,000 tons of slag over the last six centuries (Robion-Brunner et al. in preparation). This estimate makes the Bassar district one of the most important iron centers in West Africa.

As elsewhere on this continent, the direct method of obtaining iron was used. Macroscopic analysis of the slags shows that external slags are in the majority in the Bassar region but that they are accompanied by other types of internal slag. In total, seven types of slags divided into five iron assemblies are characterized on the Bassar sites. This diversity of techniques corresponds to both different time periods and different geographical locations. Apart from an iron tradition present at all times and throughout the region, it seems that there was a technical change around the sixteenth century and that the processes differ on either side of the Katcha River. In the eastern sector, two technical traditions appeared at the beginning of the thirteenth century, and then a third one appeared in the middle of the fifteenth century in the northern part. In the western sector, the southern and northern parts are not contemporary. In the south, metallurgy seems to begin at the end of the thirteenth century and end at the beginning of the fifteenth century. Two techniques are used together but not on the same sites. In the northern part, the iron industry began in the sixteenth century. On these sites, two technical traditions are used in parallel, but not with the same intensity.

The surveys and excavations conducted at Tado by the team of Dr. Aguigah Dola have identified many metallurgical sites (Aguigah 2015). After analysis of the data, it has been established that it is a natural-run, semiunderground, flared-base furnace with a conical upper part.

This diversity of remnants and iron metallurgical sites is evidence of the importance of this industry at the technical, economic, military, and sociocultural level.

Ancient Metallurgy of Iron and Society

The History of techniques cannot, however, be done outside of society, culture and thoughts that constitute a whole with the technique strictly speaking. Indeed, the technique which is the peculiarity that man has to invent the tools and the processes to act on his environment in a sustainable and reproducible way is most often the reflection of culture, society, and thought, in a word of the Homo technicus in Its environment (Garçon et al. 2010: 11).

The Ancient Metallurgy of Iron in Society

The introduction of ancient iron metallurgy has profoundly affected African societies. Indeed, this industry has been at the base of the formation of strong, powerful, and structured states in Africa. Its role in the structuring of societies has been decisive in many socioeconomic and political upheavals. Its military and political consequences

have been an important lever in the establishment of many kingdoms and empires during the African Middle Ages. Indeed, during the time of the African Middle Ages, the control of the iron mines and the control of iron gave a certain economic and military power to the different kingdoms and empires which succeeded one another: the empire of Ghana (VIIe in XIe century), Mali (from the thirteenth to the fourteenth century), and Songhai (middle of the fifteenth to the sixteenth century). Their political, military, economic, and social history illustrates the importance and role of iron in the organization and structuring of these societies.

In addition, iron, tenacious, ductile, and malleable, which has improved weapons, will also play an important role in agricultural yields, as the increase in iron production has fueled trade.

Indeed, iron has been the basis of an important agricultural revolution and dynamic trade in West Africa. Metalworking allowed blacksmiths to make various tools used in agriculture. This unavoidable material in agriculture has therefore played an important role in agricultural production. The consequence is the multiplication and increase of agricultural resources. For the African continent, trans-Saharan trade has been an exchange network where iron played an important role after that of gold. Other commercial networks have existed and participated in this dynamic trade.

During the production of iron in furnaces and forging, man has developed over the years innovations of several kinds. The techniques developed have evolved over time but also in space. They improve, transform, and evolve to the rhythm of human thought and adapt to the context of the moment. What are the innovations in iron metallurgy?

Technical Changes and Societies

At the level of the operating chain, the technical changes are especially noticeable today at the level of the work at the forge. Experiments have also revealed the use of new equipment. In the same way the raw materials and the products have changed according to the context and the new needs of the society. Blacksmiths continue to use traditional technical gestures when necessary. Their role in society has also changed over time. At the level of the smelting of iron ore, for experimental reasons, the resumption of this activity for educational and research purposes allowed the use of new materials to facilitate the work, most often because of the absence of the iron ore old material that is difficult to reproduce, inappropriate, or low yielding. As an example, the 2005 experiments in Park W, part of Burkina Faso, for the construction of the bellows furnace, the nozzles connected to the blower jars, usually made of earth, have been replaced by modern iron pipes. However, of all these changes, changes in the forge are related to the current needs of companies in sub-Saharan Africa. These mutations are visible in many African societies. In this chapter, we discuss the case of mutations in Burkina Faso where important studies have been conducted.

Mutations Related to the Equipment or Operation of the Forge

As the techniques are evolving, many blacksmiths have released their creative genius to adapt traditional techniques to the reality of the moment, modernity, and the environmental context.

The workshop itself has changed. Forging workshops vary from one region to another but also according to blacksmiths and production techniques.

Zakaria Lingani writes that “the traditional workshop is a set of places in the house. It is a shed built outside the concession with a straw roof placed on some posts” (Lingani 1988: 66).

But, nowadays, it is not uncommon to see iron poles supporting the forge shop as found in Gourcy in north and west central Burkina Faso.

In the same way the sheet is introduced in the construction of the workshop like roof, which did not exist formerly. Also, the use of a plastic tarpaulin above the roof is an introduction to modernity in the workshop. All these innovations in the forging workshop are the fact of the popularization of iron material and the availability of these different raw materials, more accessible nowadays.

In terms of technical changes and innovations, the equipment of the forge workshop has also changed. In the device for manufacturing objects,

the use of an electric coil is used instead of traditional wind tunnels. This electric coil is a recovery equipment of old cars originally used to cool the engine of vehicles. It plays an important role in the energy production system and in the operation of production. This original duct system for the fireplace blower is used by Adama Traoré, a smelter in the village of Kolonkani-Ba (Burkina Faso). Many blacksmiths use this system.

The innovation also lies in the use of a battery in blacksmith shops for the operation of the forge (in Kolonkani-Ba, Sabou, and Ouagadougou). It is a battery, usually 12 volts, intended to supply the electrical circuit of cars. Similarly, solar panels are used to power the home. For example, the modernization of Adama Kindo forging has two wind tunnel systems, one manual and the other solar. The manual system is used in case of solar energy failure.

Also, the frames of mussels formerly made of earth are also made of wood precisely boards used in the process of production.

In Sabou, a town located 100 km west of Ouagadougou, many forges are semi-modern. The forge shop is characterized by a shed under which are found, as a working device, a fireplace built of clay bricks, a ventilation system materialized by a bicycle or motorcycle man, and a darned air brewer from a motorcycle chain cover.

The raw material is obtained from recovery equipment such as rims of motorcycles and vehicles, motorcycle coils, old cooking pots or old aluminum dishes, old empty cans of drinks cans, plates, and all other object containing aluminum.

Formerly intended to produce blades of hoes, arrows, and objects of adornment, the productions are today very varied. A diverse range of tools is manufactured in its semi-modern workshops. These include groundnut shellers, single plows, multipurpose plows such as plowers, seeders, plotters, weeders, and scrapers.

In order to participate in the Tougan agricultural and craft fair in 1989, the Souabo and Toungaré family produced iron from which they pulled a plow. Iron and plow were presented at the fair.

From the technical point of view, faced with the invasion of the industrial metal and the profusion of the artisan welders, the blacksmiths had to learn to adapt. The smelting gradually disappeared at the beginning of the twentieth century, and production has also changed. Some objects remain unavoidable and unequaled, among which tools for working wood and earth are still produced by craftsmen. Some blacksmiths have made a radical change in their production (Léonce 2009: 67).

Technical progress evolves in time and space, and man uses his creativity to evolve his techniques according to his environment. The mechanism created by Adama Traoré in the village of Kolonkani-Ba shows how modern elements can be used to lighten work and obtain better returns. It also denotes the inventive spirit and continual changes in techniques.

The Metallurgists-Smiths from Yesterday to Today

In the majority of blacksmith companies, the vision of iron in African societies has also marked the various roles played by the blacksmith, an important and unavoidable figure.

The place of the blacksmith in these societies is closely linked to the image of iron, its conception in these societies where the metallurgical industry is related to ritual aspects. Indeed, techniques and rites are complementary and inseparable. In Burkina Faso, in some blacksmith societies, apart from its technical contribution through the production of iron, the blacksmith is the very one who is at the center of cultural life. The blacksmith plays distinct roles according to the societies to which he belongs. Being a blacksmith is a vocation, one is often born blacksmith, one works iron, and one carries out also important missions in the company, like that to calm the conflicts. The blacksmith, a central figure in society, is at the beginning and end of life. He heals the body and the spirit, protects, and advises. The blacksmith is also asked for his mediating role in conflicts. The blacksmith within these companies becomes a key figure.

These roles have continued in the villages because the blacksmith is still feared and respected in the majority of societies.

In the past, the production of iron and the work at the forge were an activity most often exclusive according to the blacksmith companies. In fact,

iron metallurgy was the main activity, but not permanent, because trade or barter was able to cover the needs of the blacksmith. During the drought period, he was looking for his ore, reducing it to have a good reserve of magnifying glass. In the rainy season, during which the demand for finished products increases, he devotes himself to forging, trade, and/or trade. But with the gradual cessation of iron production and the introduction of salvage iron, metallurgists and blacksmiths intensified field work. Nowadays, blacksmiths are also farmers, and the work at the forge has become a complementary activity.

Their ancestors were metallurgists. They worked on natural draft or bellows furnaces. But the present generation did not participate in the different operations. They remain today blacksmiths, farmers, and healers.

Conclusion

The approach highlights the complexity and diversity of the old iron metallurgy in West Africa. The process of developing the metal from the search for ore to the transformation of the magnifying glass into finished products reveals a wealth and diversity of operations. The variety of furnace shapes, ore processing, smelting, and refining operations is a fundamental feature of iron metallurgy in West Africa. Thanks to the ethnographic approach, we know how the metallurgists produced the iron magnifier. The ethnographic aspects shed light on the archaeological data and show indeed a certain technical richness which includes knowledge, botanical, mineralogical, meteorological, and other related fields. The protection of these technical knowledge and archaeological sites related to iron metallurgy is more than an emergency. Archaeological remains that have been abandoned for some time may disappear without proper study or development. The protection of this technical heritage makes it possible to safeguard a wealth that contains technical, educational, moral, and symbolic values for West Africa. Research on the ancient metallurgy of iron must emphasize the technical, sociocultural approaches of each society and deepen local studies because the data of current investigations have shown technological and sociocultural wealth that differ from a society to another at reduced scales.

Ironbridge Gorge Museum Trust (IGMT)

Roger H. White
Ironbridge International Institute for Cultural Heritage, University of Birmingham, Birmingham, UK

Basic Information

The Ironbridge Gorge Museum Trust (IGMT) (http://www.ironbridge.org.uk/about_us/ironbridge_gorge_museum_trust/) is an educational charity founded in 1967 within the New Town of Telford, Shropshire, in the English West Midlands. The Trust is one of the largest independent museums in the UK, hosting over half a million visitors every year and generating over £20 million income for the region (IGMT n.d.). IGMT specializes in the preservation and interpretation of the remains of the earliest phases of the industrial revolution based on the presence of two monuments critical to the development of industrial-scale iron smelting and mass production of cast iron: the Darby Furnace, site of the first smelting of iron ore by coke in 1709, and the world's first cast iron bridge (1779; Cossons and Trinder 2002). The significance of these sites was recognized in 1986 when the Ironbridge Gorge was designated as a World Heritage Site.

Major Impact

From its earliest times, IGMT has been instrumental in preserving and conserving the industrial heritage of the Ironbridge Gorge and holds 36 historic properties, some of which are accessible to the public through the museums. Increasingly, there has been a realization that these monuments are located in a historic landscape that still remains largely in place and that the whole landscape is an area of deep significance that is still in need of detailed exploration, although earlier studies have been undertaken that have highlighted some of these significances (Alfrey and Clark 1993; Trinder 2005). Other key monuments in the care of the IGMT include the Darby Houses and Quaker Burial Ground, Coalport China works, Bedlam Furnace, Broseley Pipeworks, Jackfield Tile Works, and the Tar Tunnel. The museum trust also operates the Museum of the Gorge, based in a Victorian riverside warehouse, the Museum of Iron, and Enginuity, a science and technology museum, both based on the Coalbrookdale site within the former buildings of the Coalbrookdale Iron Company. IGMT's principal attraction is the site at Blists Hill which takes the existing historical elements of the site (a brick works, canal, incline plane, clay mine, and blast furnaces) and presents them as the core elements of a recreated Victorian town comprising shops, a pub, and a post office alongside historic buildings relocated from elsewhere in modern Telford, including a squatters cottage and a turnpike toll house designed by Thomas Telford. The town is populated by costumed interpreters who demonstrate the trades and industries of the period and engage with the public to explain the technologies and processes of the day. This has led to the development of a significant expertise in the creation of historic costumes which are in demand from other museums within the UK especially for use in interactive displays allowing children to "dress up" in historic costume or use modern costume based on historic examples to explain

how former garments operated (as with corsets made from modern materials to demonstrate the body-altering use of such garments).

In addition to the popular attractions presented by the IGMT, it holds nationally and internationally important research collections which have a designated status with the UK government through the Department of Culture, Media and Sport (DCMS). The most significant collections are the archives of the Darby family which are held alongside those of the Coalbrookdale Iron Company, which the Darby's founded, and the Elton Collection. This last comprises prints, drawings, paintings, books, ephemera, and artifacts relating to the industrial and transport revolutions and their social impact in Britain and abroad to a much more limited degree (Vanns 2003). Further research collections include books, prints, and papers relating to the Great Exhibition of 1851 and the life of Thomas Telford, the engineer. Other collections relate to the museums where they are located, as with the unique collection of tiles and plaster molds of decorative tile and ceramic building materials held in the original Craven Dunnill factory at Jackfield, the collection of Caughley and Coalport porcelain held at Coalport China Museum, and the decorative ironwork of the Coalbrookdale Iron Company held at the Museum of Iron. The Broseley Pipeworks hold the last surviving collection of clay smoking pipes and molds still in their original manufactory.

Ironbridge Institute

Roger H. White
Ironbridge International Institute for Cultural Heritage, University of Birmingham, Birmingham, UK

Basic Information

The Ironbridge Institute (now the Ironbridge International Institute for Cultural Heritage) (Coalbrookdale, Telford TF8 7DX; http://www.birmingham.ac.uk/schools/iaa/departments/ironbridge/index.aspx) is a postgraduate research and teaching institute founded in 1981 as an equal partnership between the Ironbridge Gorge Museum Trust (IGMT) and the University of Birmingham. It is based in museum buildings within the Coalbrookdale valley, Shropshire, UK, adjacent to the IGMT administrative buildings. Teaching and research initially focussed on industrial (i.e., historical) archaeology, building on the collections and activity of the IGMT in rescuing the relics and investigating the remains of the industrial revolution in Britain. Ironbridge staff and students under its first directors, Michael Stratton and Barrie Trinder, were instrumental in developing the methodological approaches to historical archaeology epitomized by thematic surveys of the automobile industry in Britain (Collins and Stratton 1993) and extensive survey's of key industrial structures such as the model farm complex at Leighton, Powys, in conjunction with the Royal Commission on the Ancient and Historical Monuments of Wales

(RCAHMW). Their early work in promoting The International Committee for the Conservation of the Industrial Heritage (TICCIH) following the founding congress of the organization at Ironbridge in 1973 led to the production of the first global survey of industrial heritage (Trinder 1993). Barrie Trinder in particular was also instrumental in demonstrating the value of oral history in the recording of the experiences of former workers in the many industries within the Gorge (Trinder and Cox 1980), a program that he pursued using local people who themselves went on to carry out extensive research into the past histories of the working communities of the area (Jones 2009). In this work, they were aided by the presence of the IGMT's active commercial archaeological unit, Ironbridge Archaeology, that was able to pursue the ongoing recording of the industrial archaeology of the buildings owned by the museum, within the immediate area of Telford and Shropshire and elsewhere in Britain.

Major Impact

From 1989, Heritage Management (equivalent to Cultural Resource Management) was added to the institute's portfolio, the first program of its kind in the UK. This has become the mainstay of the institute, and distance learning versions have been added since 2005. The industrial archaeology program has been replaced since 2006 by one in Historic Environment Conservation that offers practical training in built environment conservation within a framework of legislative and ethical practice. In all more than 1000 students have been trained at Ironbridge, and graduates are to be found all over the world. Research conferences on World Heritage (Ironbridge Gorge became a World Heritage Site in 1986) and on early industry have been published (White and Carman 2007; Belford et al. 2010), reflecting the continuing role of the institute in fostering high-level research in its areas of interest. World Heritage will become the driving force behind future developments as Ironbridge Institute seeks to develop its educational role in training and management of World Heritage Sites. The annual Ironbridge Lecture offers an opportunity to engage the academic community and the public with recent speakers including Sir Neil Cossons and Adam Hart-Davies.

Iroquoian Archaeology

Jennifer Birch
University of Georgia, Athens, GA, USA

Introduction

Iroquoian archaeology is primarily concerned with the material remains of societies that inhabited the Lower Great Lakes and St. Lawrence Valley regions of the Northeastern Woodlands of North America after approximately A.D. 1000. Iroquoian peoples shared a number of cultural traits, including settlements surrounded by palisades enclosing bark-covered longhouses; subsistence based on maize horticulture supported by hunting, fishing, and gathering; a social structure organized around matrilineal descent and clan membership; and political organization based on village councils, nations of affiliated villages, and regional confederacies. Although these societies experienced dramatic population loss and upheaval in the context of European contact and colonialism, many Iroquoian peoples continue to reside in the region today.

Iroquoians were shifting horticulturalists who relocated their village sites every 10–40 years due to depletion of the local environment or sociopolitical motivations. Settlements usually relocated a few kilometers away, often in the same drainage, although longer migrations also took place. The result is an uncommonly dense record of sequential village sites that permit the reconstruction and investigation of human behaviors at a generational scale.

From a global perspective, Iroquoian archaeology can shed light on many of the key themes in archaeological inquiry. This includes processes of ethnogenesis and cultural differentiation, the spread and adoption of domesticated plants, the development of settled village life, warfare, processes and outcomes of settlement aggregation, and the development of confederacies. During the era of European contact and colonization, Iroquoian peoples weathered epidemic diseases, displacement from their ancestral lands, hostility from European forces, and entry into the global political economy.

Definition

The term "Iroquoian" refers to both a language family and a cultural pattern. Iroquoian languages are indigenous to eastern North America and include Southern and Northern branches. The only known Southern Iroquoian languages are dialects of Cherokee historically spoken by populations in North Carolina, and now Oklahoma, following the forced relocation of those groups in 1838. Northern Iroquoian languages include dialects spoken by populations inhabiting, southern Ontario, the Finger Lakes region and Mohawk River valley of New York, the Susquehanna Valley, and the St. Lawrence River Valley at the time of sustained European contact in the late 1500s and early 1600s. Iroquoian archaeology is traditionally concerned with archaeological remains thought to represent the ancestors of or historical sites related to these Northern Iroquoian speakers.

At the time of sustained European contact in the early 1600s, Northern Iroquoian peoples consisted of a small number of political confederacies, together with other groups of allied communities, each of which inhabited discrete territories (Fig. 1). The Wendat (Huron) confederacy occupied the area between Lake Simcoe and Georgian Bay and comprised four nations: the Attignawantan, Atingeennonniahak, Arendarhonon, and Tahontaenrat. The Tionontaté (Petun) were allied with the Wendat and lived southwest of Georgian Bay, near the Blue Mountains. The combined population of the Wendat-Tionontaté prior to the spread of European epidemics in the 1630s was approximately 30,000 people occupying more than 20 villages (Warrick 2008). Prior to coalescing in their historic territories, ancestors of these groups also occupied multiple drainages flowing south to the north shore of Lake Ontario. The Attiwandaron (Neutral) lived in the Grand River valley and on the Niagara Peninsula, which separates Lakes Erie and Ontario.

Iroquoian Archaeology, Fig. 1 Locations of Northern Iroquoian populations before and at the time of European contact

The Haudenosaunee (Iroquois) confederacy lived in separate nation-based territories spread across the Finger Lakes and Mohawk Valley regions of central New York State. They included (from west to east) the Seneca, Cayuga, Onondaga, Oneida, and Mohawk. The Haudenosaunee population was approximately 20,000 (Jones and DeWitte 2012). There is evidence for significant continuity in the occupation of the regions inhabited by these groups from the 1300s to the present day.

Not a great deal is known about the Wenro, who lived east of the Niagara Peninsula or the Erie, who lived south of Lake Erie. The material culture and mortuary assemblages of the Erie and Attiwandaron are similar, and both groups may have originated among populations in southwestern Ontario. The Susquehannock lived in a few large villages in the Susquehanna River Valley. As was the case for the Tionontaté and Erie, they may not have relocated into their historic configuration until late precontact or early contact eras. Iroquoian-speaking communities that populated the St. Lawrence Valley are referred to collectively as St. Lawrence Iroquoians although they were divided into distinct village clusters or "provinces" and do not seem to have shared a common political identity. By the time Champlain arrived in 1603, villages observed by Cartier in the 1530s had "disappeared." Archaeological and linguistic evidence suggests these populations amalgamated with other Iroquoian- and Algonquian-speaking neighbors.

Development of Iroquoian Societies

After approximately A.D. 1000, recognizably Iroquoian sites appear in the archaeological records of southern Ontario and central New York. These are typically small, palisaded villages less than a hectare in size with incipient longhouses that

essentially functioned as base camps for small groups practicing some agriculture. Between A.D. 1000 and 1300, maize only constituted a small portion of the diet for populations who remained committed to broad-based subsistence strategies. After ca. A.D. 1250–1300, the first longhouse villages emerged in the context of an increasing commitment to agriculture and year-round village life. This represents the "Neolithic transition" in the northeast. Distinctive patterning in material culture and burial practices suggests a certain amount of cooperation and integration between groups inhabiting subregional territories. Between A.D. 1300 and ≈1500, Iroquoian communities in New York and Ontario expanded long-distance interaction within each region, generating recognizable cultural patterns that presage the confederacies that would develop later (Birch 2015; Hart et al. 2016). Ancestral Wendat populations expanded north and east into territories that would become the contact-era footprint for the confederacy. Iroquoian settlements also appear in the St. Lawrence River Valley at this time, ca. A.D. 1350. In upper New York State, it is unclear if the earliest St. Lawrence Iroquoian settlements were the result of in situ development or movement of small groups north from the eastern Finger Lakes (Abel 2017). Further downstream, ceramic continuity from the preceding Middle Woodland suggests local in situ development (Gates St-Pierre 2009).

After ca. A.D. 1450–1500, there is evidence for increases in violent conflict throughout Iroquoia. Villages shift away from major drainages and into locations that are more defensive. By A.D. 1500, the archaeological record attests to widespread processes of coalescence. Within a generation or two, settlements become fewer in number, larger, and surrounded by multi-row palisades (Birch 2015). Some communities include more than 50 longhouses and populations close to 2000 individuals (Birch and Williamson 2013a). Ethnohistoric records suggest conflict involved raiding by small groups of men, and the archaeological record includes ample evidence for trophy-taking and prisoner sacrifice (Williamson 2007). It is unclear whether hostilities took place between adjacent communities or between groups farther afield. However, there is no evidence for the emergence of confederacies until the later sixteenth century, although alliances were certainly possible. Increased conflict likely contributed to shifts in regional settlement patterns: Ancestral Wendat settlements continued to relocate northward, culminating in the abandonment of the north shore of Lake Ontario by A.D. 1600. In upper New York State, sites clustered into what would become the territories of the Five Nations of the Haudenosaunee. The St. Lawrence Iroquoian populations inhabiting upper New York State and the eastern end of Lake Ontario dispersed, and the appearance of large quantities of distinctive SLI artifacts on sites associated with nascent nations of the eastern Haudenosaunee and Wendat suggests the integration of these populations (Engelbrecht 1995; Ramsden 2016). The outcomes of fifteenth- and sixteenth-century coalescence and conflict included the genesis of "tribal" nations (Birch 2015). Nations were composed of allied communities that shared common territories and acted in concert to achieve sociopolitical and economic objectives. In the late 1500s and early 1600s, certain of these nations allied into the historically documented confederacies.

Historical Background

Ethnohistoric texts written by Europeans who visited and colonized eastern North America in the sixteenth through eighteenth centuries, including the voluminous Jesuit Relations and accounts by Samuel de Champlain, Gabriel Sagard, and Joseph-François Lafitau, have profoundly impacted our understandings of Northern Iroquoian archaeology. While we must be cautious of projecting contact-era practices and behaviors into the past, these documents have provided a wealth of interpretive fodder for archaeologists. For some, the identification of sites associated with historical documents was important in guiding early excavations, including the search for European trade goods, early mission sites, and the routes and stopping places of European explorers.

While an antiquarian interest in "Indian relics" existed since the widespread European settlement

of the northeast, Iroquoian archaeology emerged as a formal field of inquiry in the mid-twentieth century, at a time when Americanist archaeology was concerned primarily with issues of taxonomy and chronology. In both Ontario and New York, culture-historical taxonomies were developed that ordered sites into broad cultural sequences. These were generally based on ceramic sequences and typological change. Although some culture-historical taxa have been retained as convenient shorthand within the region, most researchers prefer to focus on socially and spatially defined phenomena that relate to periods of cultural development or events that transformed the social, political, and economic fabric in meaningful ways.

The emergence of settlement archaeology as a discrete research focus in the mid-to-late twentieth century had a profound effect on Iroquoian archaeology. A series of influential studies and dissertations defined site relocation sequences and the emergence of "tribal" nations. In Canada, Bruce Trigger profoundly influenced the trajectory of Iroquoian studies. While known internationally as a theorist and historian of archaeology, Trigger was also the foremost ethnohistorian of the Wendat (Huron). From the 1970s until his death in 2006, Trigger and his students produced a generation of studies that focused on narratives of demographic, ecological, and cultural process that intersected at multiple temporal and spatial scales (Pearce et al. 2006). In New York, the essential focus on settlement archaeology has been the same. Bill Engelbrecht, Dean Snow, and their students provided a similar degree of coherence to research trajectories, including pioneering the use of geographic information systems (GIS) in the region where researchers explored issues related to settlement ecology and demography to great effect.

In Ontario, progressive cultural resource management legislation has resulted in the complete excavation of dozens of village sites. This rich corpus of settlement data have permitted the analysis of intra- and inter-site patterns regarding material culture and the built environments of individual settlements, site relocation sequences, and regional phenomena as well as comparisons between those units of analysis. The application of new conceptual frameworks (e.g., Creese 2012) and techniques, including geophysical prospection (e.g., Glencross et al. 2017), elemental analyses (e.g., Hawkins et al. 2016), isotopic analyses (Pfeiffer et al. 2017), and social network analysis (e.g., Hart et al. 2016), has led to greater theoretical and methodological plurality in Iroquoian studies in recent years.

Key Issues/Current Debates

Northern Iroquoians occupy a linguistic and cultural "island" in a "sea" of Algonquians. This position in the culture-historical map of eastern North America has led to a great deal of speculation on the origins of Iroquoian peoples. In the twentieth century, this debate involved two perspectives: One that favored the northward migration of Iroquoian-speaking farmers from the south and another that preferred an in situ development from earlier Middle Woodland populations. Early debates relied solely on ethnographic and archaeological evidence, while contemporary perspectives draw new insights from linguistics and molecular biology. While the debate over Iroquoian origins has not been resolved, contemporary researchers reject overly generalized theories, acknowledging the complexity of ethnogenesis and the variable trajectories of development for different subregional groups.

Recent studies have documented and theorized the adoption and spread of maize horticulture (Hart and Lovis 2013), including the relationships between maize and the emergence of settled village life. Isotopic studies of dietary contributions of maize, fish, and deer have revealed stability in the consumption of agricultural products but significant variability in sources of protein (Pfeiffer et al. 2016). Other work has revealed how weaning patterns relate to broader sociopolitical and historical trends (Pfeiffer et al. 2017) including the human outcomes of agricultural intensification and the effects of conflict and European contact.

The rich corpus of settlement data in Iroquoian archaeology has permitted new insights into

processes of settlement aggregation and concomitant developments in organizational complexity and diversity (Birch and Williamson 2013a). This includes aspects of community planning, the creation of public spaces, specialized production, waste management, and long-distance interaction (Birch and Williamson 2013b). Processes by which migrants and newcomers were integrated into preexisting village populations are also a fruitful area for research (Ramsden 2016). Organizational changes which came about as the result of coalescence and conflict may have been a factor which helped to both facilitate and motivate the reorganization of communities into nations and nations into confederacies during the sixteenth and early seventeenth centuries.

The so-called disappearance of Iroquoian populations inhabiting the St. Lawrence and relatedness of SLI to other groups has been the subject of perennial debate, although it is now clear that the relocation of these groups was typical of the flexible and adaptive settlement strategies practiced by Iroquoian peoples. Recent research has demonstrated that St. Lawrence Iroquoian populations inhabiting the upper portions of the valley served as brokers between groups in Ontario and New York (Hart et al. 2017) before many were incorporated in some fashion into those same populations (Engelbrecht 1995; Ramsden 2016). The relationship between St. Lawrence Iroquoians and the Huron-Wendat Nation is a topic of particular interest to modern descendants (Warrick and Lesage 2016).

Issues related to the timing and reception of European goods and direct European contact with various Indigenous populations has long been a subject of inquiry. While the study of trade goods has long been restricted to chronology building or reconstructing trade routes, contemporary perspectives also acknowledge the importance of processes of cultural entanglement, autonomy, and resistance to European influences (e.g., Jordan 2013). Elemental analyses (e.g., Hawkins et al. 2016; Michelaki et al. 2013; Pavlish et al. 2018) have also advanced understandings of the sources and distributional patterns of certain materials.

International Perspectives

Despite the fact that Northern Iroquoian societies of northeastern North America underwent many of the major transformations of interest to archaeologists and anthropologists, there has been little sustained interest in the field from outside North America.

Recently, increased collaboration between scholars in Canada and the United States has led to the development of new data sets and publications exploring processes and links that involve populations on both sides of the border. One notable example is the construction of a data set that includes coded ceramic collar decoration by John Hart and colleagues that includes 234 sites, each with a minimum of 25 distinct pots and a total of 70,463 coded collars. These data have provided the means of understanding differences in network topologies and relations between groups in Ontario, Quebec, and New York (e.g., Hart et al. 2016, 2017).

Interest in Iroquoian archaeology has come from scholars abroad engaging with structurally complementary social formations, such as longhouse societies in northern and eastern Europe or societies organized into confederacies. The large, aggregated village sites of the sixteenth and early seventeenth centuries are also excellent testing grounds for exploring processes associated with urbanization in nonurban contexts.

Future Directions

Future research trajectories in Iroquoian archaeology are poised to make major contributions to the field. Numerous researchers are currently engaged in utilizing the advances in radiocarbon dating to construct high-precision relative chronologies for numerous site relocation sequences. This work will reframe key cultural processes by aligning ceramic and absolute chronologies and permitting still-finer scale refinements of our understandings of, for example, coalescence, conflict, and the introduction of and resistance to European influences. Other ongoing research in the

archaeological sciences, including isotopic analyses and work on genetic variation, promises to yield new insights into Iroquoian history and society.

Over the last two decades, collaboration between Indigenous communities and archaeologists is becoming more common in Canada and the United States. The inclusion of First Nations communities in determining the nature and direction of research and in the production and dissemination of results is an important step toward reconciling differences between archaeologists, First Nations, and the colonial legacies in which our practices are enmeshed.

Isaacson, Ken

Kylie Lower-Eskelson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Ken Issacson, Waanyi man, is Indigenous Australian archaeologist from the gulf region, north of Mt. Isa, Queensland, Australia.

Major Accomplishments

Ken Isaacson is an Indigenous Australian archaeologist with over 25 years of experience in the field. He traces his Aboriginal ancestry though his Waanyi mother and grandmother from the gulf region of Queensland, north of Mount Isa (Isaacson 2010). Throughout his career, Ken has reached both national and international standing within Indigenous studies and has remarkably done so without institutional support from a university or government body.

Ken was educated in Mount Isa, leaving school at age 14 to join the post office, first becoming a telegram officer and then a postman. He then worked a variety of jobs until finding himself in Tambo, Queensland, at the age of 18 where he visited his first Aboriginal art site (Blacks Palace). Ken found the heritage site which also contained Aboriginal burials in a bad state of repair, and it was this experience that set him on the path of becoming an archaeologist. Having left school early, Ken realized that taking the path of a traditional university student was not for him, but he was not deterred. With the encouragement of his mother and grandmother, he set out recording and photographing archaeological sites, working both at home in Queensland's gulf country and Australia wide. Ken is passionate about documenting and preserving cultural heritage so that it can be passed on to future generations and has devoted his life to this cause.

Ken initially learned about heritage sites from station workers (both Aboriginal and non-Aboriginal) who gained an intimate knowledge of the land while mustering cattle. In other instances he learned about archaeological sites and stories from Indigenous elders. Ken's cultural knowledge eventually came to the attention of archaeology departments in Australian universities, which led to him taking students to visit the sites he was managing (now over 1,500 rock art and burial sites). Through Ken's exchanges with the universities, he learned new techniques to use in his work while simultaneously teaching students about Aboriginal culture and heritage.

As his networks within the university system expanded, Ken has become involved in archaeological seminars presenting his papers "bushman

style." He has been a member of the World Archaeological Congress for 15 years, as well as having been involved with a number of other international conferences. Ken's work includes the presentation of a paper at the Fulbright-sponsored symposium "Indigenous Cultures in an Interconnected World" in Darwin, a trip to Borneo organized by the World Wildlife Fund to visit the Dyak people, as well as trips to visit rock art sites in South Africa and the United States.

Ken has drawn on his heritage (having an Indigenous mother and father of English and German heritage) to explore the relationship between archaeology and Indigenous peoples. This has led to a particular focus on ways for Indigenous people to become more involved in their own sites, while working together with non-Indigenous archaeologists (Isaacson 2010). In *Looking Forward—Looking Back: Shaping a Shared Future*, Ken argues that archaeological theory and practice should be grounded in the recognition of the rights of contemporary Indigenous peoples over their heritage. He challenges archaeologists to work with Indigenous youth and giving them "pride in their past, self-esteem in their present and some hope for the future" (Isaacson and Ford 2005: 242).

Ken's experiences have led him to a unique position from which to articulate the need for archaeologists and Indigenous peoples to work together. He argues that archaeologists making long-term commitments to Indigenous groups can foster trust and respect and create more than just a working relationship, but a personal relationship (Isaacson and Ford 2005: 340). Ken has identified that many Aboriginal communities have immediate needs beyond those of archaeological sites which could be addressed in joint projects with archaeologists. For example, he argues that archaeologists can assist Indigenous communities in lobbying government and mining companies for support in heritage matters and to assist communities in enterprises such as developing cultural tourism ventures. Ken notes that although archaeology cannot provide all the answers or solve all the problems, in long-term relationships with Indigenous groups, the archaeological profession can be shaped into one in which profound benefits are available to Indigenous people, helping Indigenous people and cultures survive.

Ken's published works include chapters in *Indigenous Archaeologies: Decolonising Theory and Practice* and *Being and Becoming Indigenous Archaeologists*. Ken has also been involved in cross-cultural awareness programs that simultaneously teach new mine employees about Indigenous culture while cultivating respect for it. Ken is currently on the board of Southern Gulf Catchments as Director for the Greater Mount Isa Indigenous sector where he works to identify Indigenous projects in need of funding, while continuing his work mentoring archaeology students.

Islamic and Crusader Archaeologies

Katia Cytryn-Silverman
Institute of Archaeology and Department of Islamic and Middle Eastern Studies, The Hebrew University of Jerusalem, Jerusalem, Israel

Introduction and Definition

The disciplines of Islamic and Crusader archaeology, despite sharing some common chronological

and geographic frameworks within what can generally be termed the *medieval archaeology of the Levant*, have largely taken separate paths since the advent of archaeology in the nineteenth century. "Islamic Archaeology" is a generalizing term that refers to the study of the material culture produced by and/or for Muslims (specifically on the *archaeology of Islam*, see Insoll 1999: 1–9), as well as of non-Muslims living under Islamic rule (perhaps better denominated the *archaeology of Islamic lands*, encompassing a large geographical body spreading from Spain and North Africa as far as the Far East). "Crusader Archaeology," however, is a term of a narrower scope, both in time and space. It is identified with the study of the cultural remains produced during the Crusades by the Crusaders, as well as with the associated Frankish settlement. This division of research has proven inefficient at times, especially as archaeological periodization might refer to historical periods in which both Islamic and Frankish rules overlapped. For example, how precise can the archaeologist be in defining whether an excavated context in Jerusalem dates to the Crusader or Ayyūbid periods, unless provided with precise finds such as inscriptions, coins, or imports, given that Jerusalem was in Crusader hands from 1099 to 1187 and then again from 1229 until 1244?

Historical Background

The division between the two disciplines is historical and has its roots in a colonialist and Eurocentric society. Crusader archaeology had already become a focus of interest to Westerners in the early nineteenth century, partly following the nationalist appropriation of the Crusades by countries such as France, Germany, and England (Ellenblum 2007: 18–31). In addition, concern towards the Christian community and its monuments in the Levant following the massacres in Lebanon and Syria in 1860 gave further impetus to this interest in Crusader heritage (Kennedy 1994: 2).

The first reason, nevertheless, seems to have been pivotal. One of the first architectural treatises to deal with the ancient Levant was Melchior de Vogüé's (1848–1910) *Les Églises de la Terre Sainte*, pinpointing the interests of French academics and the public at that time. But to demonstrate how difficult it is to disconnect Crusader and Islamic archaeology, de Vogüé's description of the Temple Mount in this very volume (Chap. 6, "Le Temple," de Vogüé 1860: 266-291; quote below is on p. 266) is the earliest modern account of the important Muslim buildings on the Ḥaram al-Sharīf of Jerusalem – al-Aqṣā and the Dome of the Rock – even if he justified their inclusion in his book on the mistaken premise that al-Aqṣā was a Justinianic church taken over by the Muslims and on the fact that the various buildings also served the Crusaders (Fig. 1):

> On ne s'étonnera pas de trouver dans un travail consacré aux édifices chrétiens de la Terre Sainte, la description de deux mosquées célèbres, Lieux-Saints de l'islamisme. L'un de ces monuments fut primitivement construit en l'honneur de la sainte Vierge [i.e. al-Aqṣā, which according to de Vogüé was erected by Justinian]; c'est une des plus anciennes et des plus belles églises de Jérusalem, usurpée par les disciples du Koran. L'autre, quoique d'origine musulmane [the Dome of the Rock], fut, pendant un siècle, consacré au culte catholique [*Templum Domini*]; il s'élève sur l'emplacement du "saint des saints"; son nom, porté avec éclat par un ordre fameux de chevalerie [Templars], est resté célèbre dans les annales du moyen âge chrétien. . .

It is also worth acknowledging that even in the more encompassing and balanced work of Charles Clermont-Ganneau (1846–1923), *Archaeological Researches in Palestine during the Years 1873–1874*, the first chapter of the first volume deals with an important subject in the field of Crusader Archaeology, being entitled "Introductory Remarks on the Distinctive and Specific Character of Crusading Masonry" (Clermont-Ganneau 1899: 1–47).

Another example of the nationalistic background for the first archaeological enterprises in the Levant is the German excavations at Tyre conducted by J.N. Sepp, B. Sepp, and H. Prutz in 1874. They were financed by Otto von Bismarck, the Imperial German chancellor at that time, and were motivated by the unfulfilled desire to find Barbarossa's tomb within what was

Islamic and Crusader Archaeologies, Fig. 1 The Temple Mount in Jerusalem during the mid-nineteenth century. (M. de Vogüe 1860: plate between 266 and 267, after photograph by A. Salzmann)

mistakenly believed to be the remains of Tyre's cathedral (Ellenblum 2007: 35–36).

But it was perhaps the magnitude of the Crusader castles encountered in Syria, Lebanon, Palestine, and Jordan that moved Western researchers most, as they best represented Western culture and power in the east. So while de Vogüé was busy studying Crusader churches, his friend and compatriot Emmanuel Guillaume Rey (1837–1916) dedicated his efforts to record to the best of his capacities the castles of the Latin Kingdom. His *Étude sur les monuments de l'architecture militaire des Croisés en Syrie et dans l'ile de Chypre* (1871) is the first scientific work on this topic from which later studies were launched (Fig. 2).

During the French Mandate in Syria and Lebanon (1921–1946), Crusader archaeology continued to flourish, "especially as the presence of Franks in the area in the twelfth and thirteenth century could give a sort of legitimacy to their presence in the twentieth" (Kennedy 1994: 5). Camille Enlart's (1862–1927) *Les Monuments des Croisés dans le royaume de Jerusalem: architecture religieuse et civile* (1925) resulted from an official commission, as did Paul Deschamps's *Les Châteaux des Croisés en Terre Sainte* (1934–1973).

For many decades thereafter, Crusader archaeology remained largely focused on castles and churches (the latter field in clear independence from Byzantine archaeology), as they best expressed the deeds of the great heroes of Europe. A more general approach to the Crusader remains in the Levant, including the study of rural and domestic life, developed much later, mainly in the 1970s and 1980s, under Israeli historians J. Prawer (1917–1990) and B.Z. Kedar (b. 1938). Archaeology only started reflecting this holistic approach from the 1980s onwards, best represented by fieldwork undertaken by D. Pringle of Cardiff University, R. Ellenblum of the Hebrew University of Jerusalem, and A. Boas of the Hebrew University and later the University of Haifa.

Islamic archaeology developed in an altogether different manner. It was not overtly driven by nationalistic or by religious sentiments (though S. Vernoit (1997) stresses how the excavations at Qalʿat Banū Ḥammad in Algeria and those in Madīnat al-Zahrāʾ in Spain served the colonialist motivations of France and Spain, respectively), but rather by the rising discipline of Oriental Studies in Europe and to a certain extent by Westerners' attraction to the "exotic" as nurtured by nineteenth-century Orientalism. Yet as argued by

Islamic and Crusader Archaeologies, Fig. 2 Reconstruction of Krak des Chevaliers (After Rey 1871: Pl. VII)

M. Rosen-Ayalon (2006: 11), the development of the field was delayed even after the end of the colonial period:

> The various Muslim countries maintained a similar archaeological policy for several decades. There was a race to discover ancient civilizations: the Egypt of the Pharaohs, Hittite Turkey, Achaemenid Persia, as well as [Iraq's] Sumer, Akkad, Babylonia, and [Lebanon's] Phoenicia.

One of the most valuable contributions to the field of Islamic archaeology of the late nineteenth to early twentieth century was Max van Berchem's (1863–1921) *Corpus inscriptionum arabicarum*, the volumes of which contain inscriptions surveyed by the author during his trips to Egypt, Palestine, and Syria between 1887 and 1914. Beyond its contribution to the field of Arabic epigraphy, this corpus is a major pillar of Islamic archaeology, due to van Berchem's discussions of archaeological/architectural findings relating to various monuments and sites as well as associated historical sources.

Yet the event which for many years and to a great degree shaped the perception of Islamic archaeology was the publication of *Ḳuṣejr ʿAmra* by Alois Musil (1868–1944) in 1902 (Fig. 3). Its impact in Europe was of a totally different nature to that made by publications of Crusader castles. This well-preserved small Umayyad bathhouse, with figurative frescoes – some of them including seminude women and men – covering most of its standing surfaces, confused those who still believed in the "unlawfulness" of painting in Islamic art (see K.A.C. Creswell's "The Lawfulness of Painting in Islamic Art," 1946). *Quṣayr ʿAmra*'s frescoes ignited the romanticism regarding the first Islamic dynasty, in which the Umayyad aristocracy was seen as a class of irredeemable Bedouins, always drawn to the desert life – the *bādia* – and its pleasures. This discourse was best represented by the biblical scholar and orientalist J. Welhausen (1844–1918), in his *Das arabische Reich und sein Sturz* (1902), later translated into English (1927).

Not long after the publication of Musil's *Ḳuṣejr ʿAmra*, the first fieldwork at an Islamic city was carried out at Sāmarrāʾ on the Tigris.

Islamic and Crusader Archaeologies, Fig. 3 Quṣayr ʿAmra. (A. Musil, c. 1901. Library of Congress Prints and Photographs Division Washington, DC, call number LOT 11356-34)

Islamic and Crusader Archaeologies, Fig. 4 Excavation of Samarra (Iraq): view of the Great Mosque of al-Mutawakkil, 1911–1913. Panorama of 3 photographic prints, 8.7 × 29.2 cm (The Ernst Herzfeld papers, Freer Gallery of Art and Arthur M. Sackler Gallery Archives, Smithsonian Institution, Washington, DC: A.6 04.20.123)

This site was first visited by E. Hertzfeld in 1903, who published a series of studies on Sāmarrāʾ from 1907 to 1948 (Fig. 4). Capital of the ʿAbbāsids between 836 and 892, at over 58 km^2, this is the largest Islamic site known to date. It holds important examples of religious and secular early Islamic architecture, many of them embellished by stucco work fashioned in three main styles, a varied repertoire of unglazed and glazed pottery and other wares. Most of all, it is famous for the 53 m high spiral minaret of al-Mutawakkil's Mosque (849–851). The rich finds from Sāmarrāʾ further contributed to – and expanded – the romantic view of Islamic archaeology, which unlike the Crusader archaeology of churches and castles developed so as to emphasize the concepts of wealth and exotica. The excavations of the Umayyad palace at Madīnat al-Zahrāʾ next to Cordoba in Spain, which commenced in 1911 directed by the architect Ricardo Velázquez Bosco (*Medina Azzahra y Alamiriya*, 1912), only added to this romantic view.

Despite the above, one cannot claim that Islamic archaeology developed around an "archaeology of palaces," in the same way that Crusader archaeology developed both as an "archaeology of castles" and an "archaeology of

churches." In fact, the next exposure of an Umayyad palace – that at Khirbat al-Minya on the northwestern shore of the Sea of Galilee – was an archaeological misinterpretation by the German archaeologist A.E. Mader, who in 1932 started excavations at the site in the belief that it was a Roman fortress. Only in 1937, after a small mosque and a large hall had been exposed in the building's southern wing, was the site finally understood as having been originally built as an Umayyad castle (*qaṣr*, *pl. quṣūr*). At that time, the Umayyad palace at Khirbat al-Mafjar, north of Jericho, was already being uncovered (1934–1948). This monumental complex of palace-bath-mosque was rich in finds, including a small piece of marble containing an inscription referring to Hishām b. ʿAbd al-Malik (r. 724–743). This artifact provided archaeologist D.C. Baramki and later R. Hamilton with a clear chronological framework for the erection and use of the palace (today it is accepted that Hishām's nephew, al-Walīd II, was the actual patron of the palace while still heir to the throne). As in the case of Quṣayr ʿAmra and Sāmarrāʾ, Khirbat al-Mafjar's unique planning and rich decoration, including many figural sculptures and the famous lion-gazelle mosaic, gave rise to further romanticization of early Islamic life in the Levant (as indicated by the title of Hamilton's 1959 publication, Khirbat al-Mafjar: an Arabian Mansion in the Jordan Valley), supported by contemporary works on the Umayyads such as H. Lammens' *Études sur le siècle des Omeyyades* (1930).

The posthumous publication of J. Sauvaget's (1901–1950) *Châteaux Omeyyades de Syrie* in 1968, in which the author highlighted the economic background for the erection of the palaces and dismissed the previous romantic approach of scholars of the late nineteenth and first three decades of the twentieth century, was a landmark in Islamic Archaeology. It not only changed the paradigm by which Umayyad palaces had so far been investigated but also established new standards by which historical sites should be interpreted. The excavation at Qaṣr al-Ḥayr al-Sharqī east of Palmyra in Syria between 1964 and 1971 is a good example of a project which adopted Sauvaget's "agricultural model," even if not in its entirety (Grabar et al. 1978: 162–163).

Another important contribution by Sauvaget to Islamic Archaeology is his publication on Aleppo's urban development (1941). Following his archaeological survey of the city in 1935, under the auspices of the local Service des Antiquités, Sauvaget not only created a remarkable record of a medieval city (Fig. 5) but also laid the foundations for the much-discussed topic of the "Islamic City." To this field he also contributed his studies on Latakiya (1934) and Damascus (1949) in Syria.

Key Issues

The study of early Islamic settlements and urban development has been central for Islamic archaeologists. In addition to Sauvaget's and Herzfeld's contributions, others have created a field abounding with views and reviews on the subject: research on North African cities both by W. Marçais (in his famous "L'Islamisme et la vie urbaine" of 1928) and by G. Marçais ("La conception des villes dans l'Islam" from 1945), on Fusṭāṭ in Egypt by G. Scanlon ("Housing and Sanitation. Some aspects of medieval Islamic public service," 1970) and W.B. Kubiak (Fustat, Its Foundation and Early Urban Development, 1988), on Ayla in Jordan by D. Whitcomb ("The misr of Ayla: Settlement at ʿAqaba in the early Islamic period," 1994), on Sāmarrāʾ by A. Northedge (*The Historical Topography of Samarra*, 2005), as well as many other case studies of urban archaeological sites (see Whitcomb 2010 for a representative listing of urban sites). A. Hourani and S. Stern's *The Islamic City* (1970), H. Kennedy's "From Polis to Madina – Urban Change in Late Antique and Early Islamic Syria" (1985), J. Abu-Lughod's "Historic Myth, Islamic Essence, and Contemporary Relevance" (1987), P. Wheatley's *The Places Where Men Pray Together* (2001), and more recently S.K. Jayyusi et al.'s *The City in the Islamic World* (2008) as well as important summaries such as those by Walmsley (2007: 71–112) and Milwright (2010:

Islamic and Crusader Archaeologies,
Fig. 5 Reconstruction plan of the city of Aleppo during the thirteenth century (After Sauvaget 1941: Pl. 58)

75–96) are essential readings for those interested in this topic.

Research on Crusader cities, on the other hand, is of a different kind. As A. Boas writes in his *Crusader Archaeology* (Boas 1999: 12):

> There was no need for the Franks to establish new cities in the East. They occupied existing cities, expanding them … Within the cities they built new public and private buildings and converted others to suit their own needs.

One of Jerusalem's earliest excavations, undertaken by C. Wilson in the Muristan (south of the Church of the Holy Sepulchre) in 1867, exposed evidence for Crusader-era urban changes in Jerusalem, in this case the Hospitallers' quarter, while searching for remains of the Herodian Second Wall (Wilson & Warren 1871: 270–273). Since then much has been learned about Crusader Jerusalem (Boas 1999: 13–24) but even more about Akko in northern Israel, which was first studied by Rey in 1879 (*Étude sur la topographie de la ville d'Acre au XIIIe siècle*) and which has been intensively excavated since 1990, with Crusader levels being found under the remains of the Ottoman city (Boas 1999: 32–41).

Within the framework of the urban archaeology of both Islamic and Crusader periods, the study of churches and mosques, or of religious institutions in general, has been cardinal. As mentioned above, "church archaeology" has played a

central role in Crusader archaeology since its outset (e.g., the early excavations at Tyre), and those interested in the period can only benefit from D. Pringle's *The Churches of the Crusader Kingdom of Jerusalem* (4 vols. 1993–2009). Unfortunately there is nothing to parallel Pringle's work in "mosque archaeology," perhaps due to the much wider chronological and regional scope of the latter. Yet mosques have always been of central interest to archaeologists and historians of Islamic art, being discussed in all monographs on Islamic art and architecture including Creswell's *Early Muslim Architecture* (1932–1940), Ettinghausen and Grabar's *The Art and Architecture of Islam 650–1250* (1987; updated in 2001 with Jenkins-Madina), and R. Hillenbrand's *Islamic Architecture: Form, Function and Meaning* (1995). A few syntheses have developed this theme, most notably the monographs by D. Kuban (series on *Muslim Religious Architecture*, 1974, 1985), T. Insoll's chapter in his *The Archaeology of Islam* (Insoll 1999: 26–59), and J. Johns' article "The 'House of the Prophet' and the Concept of the Mosque" (1999). Important discussions on the development of the mosque have appeared since the 1980s, such as D. Whitehouse's report on Siraf's Congregational Mosque (*The Congregational Mosque and Other Mosques from the Ninth to the Twelfth Centuries*, 1980), D. Sack's monograph on the great mosque of Rusafa (1996), M. Rosen-Ayalon and R. Grafman's article on the proposed plan of Umayyad al-Aqṣā's ("The Two Great Syrian Umayyad Mosques: Jerusalem and Damascus," 1999), A. Walmsley and K. Damgaard's archaeological report and discussion on the mosque of Jarash (2009), and the current author's work on the congregational mosque of Tiberias (2009).

But while focusing on the main trends and differences in approach between Islamic and Crusader archaeology, one has also to be aware of the many converging points between the two, sometimes making it almost impossible to separate the disciplines. In light of Boas' words quoted above ("They occupied existing cities. . ."), it is futile to study a Crusader city without understanding its pre-Crusader phases, while to study Ayyūbid and Mamlūk architectural and urban programs without examining the monuments and archaeological vestiges left by the Franks is also ineffectual. The Crusader interventions at the Temple Mount in Jerusalem and more specifically at al-Aqṣā mosque which served as palace and later as headquarters for the Templars, for example, can only be analyzed (and even then not with ease) in light of the background of architectural development during the early Islamic period. The same can be said for the changes and additions that followed the Battle of Ḥiṭṭīn in 1187 and the reinstatement of the building as a mosque (Hawari 2007: 192–193). This is also true regarding the erection of churches and their post-Crusader use (see St. Anne's church in the northeastern section of the city, e.g., which was transformed into a madrasa by Ṣalāḥ al-Dīn; Pringle 2007: 142–155, Hawari 2007: 187–188), the erection of public establishments such as markets and their expansion during the Mamlūk period (e.g., the Cotton Merchants' Market), and the improvement of city defenses (the Mamlūk-Ottoman citadel of Jerusalem is basically an improvement of the Crusader fortifications; Boas 1999: 17–19, based on archaeological reports by C.N. Johns).

Yet the task of a trained archaeologist or historian of art is not always easy. The Romanesque style which developed during the twelfth century, as well as certain building techniques, survived into the Ayyūbid (1187–1260) and early Mamlūk periods (1260–1310s). Unless a building consists of a dated structure, with a clear religious identity and minor later changes (e.g., St. Anne's church), identifications might be contested for generations, as in the case of al-Aqṣā's gate which uses Crusader elements. Some will argue that the slender columns, the typical capitals, and the elaborate molded archivolt with chevron, cavetto, and cyma-recta moldings are in situ and thus evidence for a Crusader monumental gate. Others will argue that this is a typical case of spoliation. Yet the presence of two Ayyūbid inscriptions, one over the archivolt attesting to the erection of the portico's façade by al-Muʿaẓẓam ʿĪsā in 1217–1218 and the other on the central bay's dome attributing construction to the same ruler (d. 1227), leaves little doubt as to the date at

I

which the earlier – Crusader – arrangement was replaced (Hawari 2007: 161–163).

Another converging point of the two disciplines is found in rural archaeology, where it is often difficult to discern the nature of a twelfth- to thirteenth-century settlement – Muslim, Christian, Frankish, or mixed – unless characterizing material finds allow such an identification. Typical ceramics of the period – such as slipped and glazed wares produced in Beirut or unglazed geometric painted handmade vessels – can be found all over the region (Avissar & Stern 2005: 88–90, 113–116). Other subjects, such as "Sugar Archaeology," are common to the Crusader, Ayyūbid, and Mamlūk periods and should thus be studied as a single unit. Sugar production, known in the Levant since the early Islamic period, was "industrialized" by the Franks during the twelfth century and persisted in the region up to the fourteenth century. The evidence at Khirbat Manot in northwest Israel, Ṭawāḥīn al-Sukkar in southern Jordan, and Kouklia in Cyprus is best preserved (Boas 1999: 81; Milwright 2010: 70-73), while excavations at Khirbat al-Minya on the northwestern shore of the Sea of Galilee have shown that the Franks took possession of the abandoned Umayyad palace (see above) and transformed it into an industrial plant, which seems to have persisted in use up to the Mamlūk period.

Future Directions

In conclusion, despite the different motifs and definitions which guided the first 100 years of Islamic and Crusader archaeology, in too many ways they join paths. The multiphased sites – urban or rural; military, religious, or secular – demand from archaeologists a broad knowledge of the material culture of the Middle Ages. Today the "archaeology of castles and churches" is much more encompassing, with interest in the communities which they served and the culture they nurtured. The same applies to the "archaeology of palaces and mosques," which has evolved to search for patterns of settlement, of land use, and of the Islamization of pre-Islamic lands.

Islamic and Maritime Archaeologies

John P. Cooper
Institute of Arab and Islamic Studies, University of Exeter, Exeter, Devon, UK

Introduction

Islamic archaeology and maritime archaeology are two relatively recent subdisciplines to have emerged within archaeology, reflecting technological innovation and new theoretical trends and avenues of inquiry. The advent of SCUBA technology has, since the 1950s, facilitated investigation of submerged sites, leading to innovative techniques in underwater survey and excavation. Meanwhile, a growing interest in "non-European" archaeologies has contributed to an increasing appreciation of past Islamic societies as a legitimate object of investigation.

Definition

As with many adjectives applied to the word archaeology, "maritime" and "Islamic" are fluid shorthands that are ultimately inadequate to the task of defining rich and complex areas of investigation. Conceptually, maritime archaeology has broadened from a relatively narrow focus on shipwrecks (Muckelroy 1978: 3–10) to cover not only archaeology done underwater but also the archaeology of all maritime-related material culture. Equally, the term "Islamic" can be taken to mean the material remains of Islam as a religion (Insoll 1999: 1–15) or defined by cultural-historical criteria, thus incorporating societies over which a political élite professing Islam held sway (Milwright 2010: 1–11), or indeed minority Muslim communities living among non-Muslims.

Key Issues

Shipwrecks

Maritime archaeology's early encounter with Islamic remains was in the form of shipwrecks. In 1973, the Turkish sponge diver Mehmet Aşkin showed a wreck at Serçe Limanı on the Turkish Aegean coast to George Bass of the Institute of Nautical Archaeology (INA). Bass led excavations at the site from 1977 to 1979, revealing an early eleventh-century CE merchantman operating between Byzantium and the Fatimid Caliphate (Bass 2004). The vessel was the earliest known example of frame-first construction and had been rigged with two lateen sails. The cargo included around 3 t of glass cullet, acting as ballast, perhaps bound for the glassworks of Constantinople. Over 80 intact glass vessels were also excavated. Ceramics included 110 Byzantine amphorae, water jugs that are probably from Egypt, glazed wares, and Levantine cooking pots, alongside Fatimid coins and coin weights. The wreck exemplifies well the problems of definition: Although much of the cargo was from the Islamic realm, faunal remains show the crew ate pork, suggesting they were Christian. The wreck is thus suggestive of Christian-Muslim exchange in a period of Fatimid-Byzantine détente.

Islamic and Maritime Archaeologies, Fig. 1 Divers from the Institute of Nautical Archaeology excavate an Ottoman wreck at Yassıada, Turkey. (Image: Cemal Pulak, Institute of Nautical Archaeology)

Also in Turkey, Bass and his team discovered a sixteenth-century CE Ottoman vessel at Yassıada, partly overlying a fourth-century CE Roman wreck on which they were working (Fig. 1). Excavations in 1982–1983 revealed a largely empty hull containing a small amount of Ottoman sgraffito-glazed bowls elsewhere associated with military contexts, as well as cannonballs (Fig. 2). The vessel, originally around 20 m long, was interpreted as a naval supply craft. The lack of cargo, even ballast, gave rise to the theory that the vessel had become stuck on the adjacent reef before sinking, allowing the cargo to be salvaged (Pulak 2005).

Islamic and Maritime Archaeologies, Fig. 2 Glazed bowls from the Yassıada Ottoman wreck, Turkey. (Image: Cemal Pulak, Institute of Nautical Archaeology)

It was not until the 1990s that further ostensibly Islamic wrecks were investigated. Starting in 1994, archaeologists embarked on an underwater survey of the Tantura lagoon, in modern Israel, led by Shelley Waschsmann of INA and Yaakov Kahanov of the University of Haifa. Tantura was a rare sheltered lagoon of the ancient Palestinian coast, and work there has revealed seven vessels dating from the fifth to the ninth centuries CE. The earliest of the Islamic-era wrecks, Tantura F, dates from the early eighth century. This 15-m-long flat-bottomed cargo vessel was made frame-first with Anatolian timber. Finds included pottery, metal anchors, and organic materials (Barkai and Kahanov 2007). Another wreck, Tantura B, dates from the early ninth century CE. This flat-bottomed hull was again built frame-first and has been interpreted as a coaster, war galley, or even Nile rivercraft (Khalilieh 2005).

All three of these vessels share their frame-first construction method with a practice found throughout the Mediterranean during the early

medieval period. The tradition stands in contrast to the shell-first, and often sewn, traditions of the Islamic western Indian Ocean region, demonstrating that shipbuilding technologies do not necessarily reflect an Islamic/non-Islamic dichotomy.

Archaeological evidence for putatively Islamic vessels in the Indian Ocean is sparse. The only medieval wreck discovered in the region is of a ninth-century CE sewn "Arab" vessel, found by fishermen off the Indonesian island of Belitung (Flecker 2001). The wreck was salvaged under license from the Indonesian government by the German company Seabed Explorations, and a comprehensive archaeological record was not made. The cargo comprised Changsha pottery from the late Tang Dynasty (618–906 CE) and imperial-quality Chinese ceramics including Ding white-ware and Yue-ware from Zhejang. While none of this cargo is identifiably "Islamic," the sewn planking of the hull led to the vessel being identified variously as "Arab," "Persian," or perhaps "Indian" and so indicative of long-distance trade in prestige goods between the Islamic world and China.

The only Islamic-era shipwreck to have been archaeologically excavated in eastern waters with license from the state is the eighteenth-century CE Sadana Island wreck, an Ottoman vessel found off Egypt's Red Sea coast and excavated by INA under the direction of Cheryl Ward (Ward 2001) (Fig. 3). The 50-m-long hull contained an assemblage of Chinese Qing Dynasty ceramics designed for Islamic markets, as well as coffee, aromatic resin, spices, and tobacco-smoking paraphernalia belonging to the crew (Fig. 4). While historical accounts of Indian Ocean commerce in the period tend to focus on European trade with east Asia, the Sadana wreck is indicative of a more local trade, particularly in coffee, conducted within the Ottoman empire, albeit one with connections to China. Little data on the hull construction has been published, although the vessel is secured with iron fittings, and not sewn.

Ships' Timbers

Apart from wrecks, timbers from Islamic-era ships have also been found reused in on-land contexts, giving further insights into past nautical technologies. Evidence of sewn ships' timbers has been discovered at al-Balīd in Oman, dating from the tenth to the fifteenth centuries CE, as well as at

Quseir in Egypt, from between the late twelfth and early fifteenth centuries CE (Blue 2006; Belfioretti and Vosmer 2010). Along with the evidence of the Belitung wreck, medieval historical descriptions such as that of the Andalusian pilgrim Ibn Jubayr, and ethnographic evidence from as late as the twentieth century CE, the sewing together of planks as part of a shell-first construction technique can be seen to constitute part of a distinct Indian Ocean shipbuilding practice lasting much of the Islamic era but also predating it: It is also mentioned in the first-century CE *Periplus Maris Erythraei*. Both the al-Balīd and Quseir timbers show the use of wooden dowels to edge-join the planks, with coconut coir rope then used to bind them. A similar technique is seen in twentieth-century vessels in the Yemeni Hadramaut and Oman as well as southern India.

Reconstructions

Archaeological and historical evidence has inspired two large-scale attempts to "reconstruct" sewn-planked medieval sailing craft, both in Oman. In 1980, a team led by Tim Severin completed the building of *Sohar*, a 24-m-long vessel that he and his crew sailed from Muscat in Oman to Canton in China (Severin 1982) (Fig. 5). More recently, from 2008 to 2010, Tom Vosmer directed the building of the *Jewel of Muscat*, a sewn reconstruction based on the Belitung wreck (Fig. 6). It sailed from Qantab in Oman to Singapore. These projects not only allowed an experimental appreciation of past technologies within the navigational landscapes in which they occurred but also provided a vehicle for Oman's self-representation as a maritime nation.

Islamic and Maritime Archaeologies, Fig. 5 Craftsmen in Sur, Oman, work in pairs to sew together the planks of Tim Severin's *Sohar* using coconut coir cordage. (Image: Severin Archive/Sindbad Voyage)

Ethnographic Research

While archaeological finds have so far yielded a relatively modest set of data on "Islamic" seafaring, ethnographic research into vessel types of the Islamic world has contributed a complementary strand of inquiry. The approach is used to understand contemporary boatbuilding practices in their own right and also to use this as a basis for the analogous interpretation of archaeological remains. It was not until the early nineteenth century CE that the Spanish spy Domingo Badia y Leblich, and later in the century the French Admiral Pâris, began to make detailed scale drawings of vessels from the region. Among English-language scholars, the term "dhow," once referring to a specific vessel type, was adopted to signify all larger "Islamic" craft of the region. Since the early twentieth century CE in particular, western scholars such as James Hornell (1942) have sought to establish a typology of regional "dhows." Color photographic books on regional craft appeared in the 1960s and 1970s, while scholarly works by Dionisius A. Agius (2008), Yacoub al-Hijji (1989), Erik Gilbert (2004), and Sheriff (2009), among others, have sought to

Islamic and Maritime Archaeologies, Fig. 7 Close observation of a large fishing *hūrī* at Khor al-Ghureira, Yemen, during asurvey conducted in 2009 by the University of Exeter's MARES Project (John P. Cooper/MARES)

study social, economic, cultural, and linguistic dimensions of the vessels and their use, partly as a response to the rapid decline in the use of these vessels. More recent research has included the University of Southampton's Huri Project, led by Lucy Blue, recording the *hūrī* logboats of the western Indian Ocean; the University of Exeter's MARES Project, led by Agius, investigating the traditional craft of the southern Red Sea (Agius et al. 2010) (Fig. 7); as well as individual efforts by Norbert Weismann and Piotr Dziamski in the Gulf. All have sought to make a more detailed illustrated record of the remaining vessels of the region. Meanwhile Julian Whitewright (Forthcoming, 2012) has tracked the emergence of the lateen/settee rig in the Indian Ocean through iconography and text, demonstrating that this rig, today seen as quintessentially Arab, has a much older, pre-Islamic, provenance in the Mediterranean and is in fact a more recent introduction to eastern waters.

Port Archaeology

The emergence of Islam prompted an upsurge in international trade in the Indian Ocean region, and despite periodic conflicts with Christian powers, trade in Eastern luxury goods across the Mediterranean was, until the Portuguese discovery of the Cape route, also overseen by Islamic powers. The Indian Ocean became an Islamic *mare nostrum*, in which mariners harnessed the region's monsoon winds to pursue transoceanic trade. Within this

system, African ports supplied slaves and raw materials such as tortoiseshell and wood; Indian ports provided textiles, timber, and food; while Middle Eastern ports exported dates and manufactured goods such as ceramics, metalwork, and carpets.

Siraf, in modern Iran, was in the ninth century CE, the Persian Gulf's main entrepôt for luxury goods and ceramics made in China or the Abbasid heartlands. Excavations conducted between 1966 and 1973 by the British Institute of Persian Studies revealed that Siraf had existed already in the Sasanian period (Whitehouse 2009). By the early Islamic period, it served the inland trading center of Ardashīr Khurra. The elaborate carved teak architecture of its buildings speaks of the port's mercantile prosperity and overseas connections. Iraqi, Sirafi, and Chinese wares found on the Lamu archipelago in Kenya and Banhore in Pakistan may well have emanated from the port. A devastating earthquake in 976 or 978 CE, combined with a weakening of the local Buyid dynasty, led to decline: Visiting it in the early thirteenth century CE, the geographer Yaqut described it as a small and poor town.

In the Egyptian Red Sea, separate expeditions by the University of Chicago, led by Donald Whitcomb and Janet Johnson (1982), and the University of Southampton, led by David Peacock and Lucy Blue (2006), have shed light on the Ayyubid and Mamluk port of Quseir, which occupied the site of the long-defunct Roman port of Myos Hormos. Quseir was connected to the Nile by a pack-animal route through the Wadi Hammamat, this being the shortest connection between sea and river in Upper Egypt. The excellent Roman-era harbor was extensively silted by the medieval period, but a small embayment remained at the lagoon mouth. Quseir was involved in the trade in spices and textiles with India, in Chinese ceramics, and in more local networks within the Red Sea region (Fig. 8).

In 1985, soon after the Chicago excavations began at Quseir, archaeologists from the Middle East Cultural Centre in Japan led by Mutsuo Kawatoko began excavations at the site of the medieval and early modern port of al-Tur, on the Gulf-of-Suez coast of the Sinai peninsula. Al-Tur was an important harbor for both Christian and Muslim pilgrims, bound for Mount Sinai and Mecca, respectively. Its Islamic heyday was between 1379 CE, when the alternative *hajj* route via the southern port of 'Aydhab was abandoned, and the end of the fifteenth century, when the Portuguese discovered the cape route to the Indian Ocean. The medieval town has been extensively excavated: Finds reveal contact with China and Southeast Asia; Turkish and European ceramics, pilgrim flasks, and glassware; and Arabic documents from the fifteenth and sixteenth centuries.

Islamic and Maritime Archaeologies, Fig. 8 Indian resist-dyed fabric with elephant design from the medieval Islamic port of Quseir, Egypt. (Image: University of Southampton)

The medieval lake-island site of Tinnis in Lake Manzala, in Egypt's northeast Delta region, has been the subject of archaeological study by the Egyptian Antiquities Service since 1978 and by Alison Gascoigne of the Universities of Cambridge and Southampton since 2004. The site's island status has largely preserved it from modern urban encroachment. It comprises the remains of a largely brick, walled city, its maritime

infrastructure including the remains of at least one intramural canal harbor, and the water gate protecting it. Tinnis probably has a pre-Islamic foundation, but its heyday was Fatimid, where it was famed for its high-status textiles industry (Gascoigne Forthcoming). Its sheltered position within Lake Manzala and onward connection to the Damietta branch – avoiding the dangerous Damietta mouth – made it a navigationally attractive location. The city was eventually abandoned in the twelfth century following a series of Crusader attacks. Geophysical investigation of the site has identified the extent of the largest of the intramural harbors. Archaeological finds on the surface suggest onward connections with China, Persia, and the wider Mediterranean region.

Outside the Islamic heartlands, archaeological investigations by Mark Horton in 1980 at Shanga, an abandoned coastal trading settlement on the Lamu archipelago, Kenya, sought to address processes surrounding the appearance of Islam along the Swahili coasts (Horton 1996). The location of the archipelago placed it ideally at a terminus of transoceanic monsoon trade; local resources such as mangrove timber and water added to its attraction. The earliest evidence of settlement is from the eighth century CE, by the end of which a small number of inhabitants were Muslim and the first wooden mosque had been built. From pottery and glass evidence, they already had contact with the Gulf region. In the tenth century, a new style of building, using coral, was adopted and used in a new mosque. A further, larger, mosque was built from this material in the eleventh century CE, suggesting a majority Muslim population by this stage. By the late eleventh–early twelfth centuries CE, pottery included Indian and Chinese Longquan imports. By the late thirteenth century, trade connections appear to have realigned to South Arabia. The site appears to have been abandoned after a violent attack in the early fifteenth century CE.

Archaeological investigation into a more recent port settlement has been conducted by the University of Copenhagen at the site of al-Zubara in northwest Qatar. Al-Zubara was a large walled town of stone buildings which reached its zenith in the eighteenth–nineteenth centuries CE, when it was an important pearling center and processor of imported dates. Archaeological work to date has mapped the extensive remains of the urban area, which was abandoned in the twentieth century (Walmsley et al. 2010). Underwater survey work is being conducted offshore by the University of Birmingham.

In Oman, recent archaeology directed by Axelle Rougeulle of the Centre National des Recherches Scientifiques has focused on the site of Qalhat, a port city founded in the early twelfth century CE that became the second capital of the kingdom of Hormuz between the thirteenth and fifteenth centuries (Rougeulle 2010). Work so far has focused on the urban layout of the town and the identification of key structures. Excavations have revealed large proportions of Indian ceramic imports, Yemeni mustard ware, and, from the thirteenth to fourteenth centuries CE, Chinese imports.

Current Debates

Given its rich textual heritage, the Islamic world raises compelling issues regarding the relationship between archaeology, history, and art history. This is nowhere truer than within maritime studies. Few archaeologists still regard themselves as embarked on a purely "scientific" inquiry into past human existence. Nevertheless the discipline continues to shed an alternative light on past societies that is not constrained by the cognitive bounds and interests of the largely urban élites who authored the majority of written works surviving from the past. Arabic sources are, for example, surprisingly limited in their descriptions of past watercraft: The level of detail disclosed by even the few archaeological and ethnographic boat studies conducted so far is vastly greater than anything surviving in written sources.

At the same time, the nature of maritime studies is such that written accounts from the past – complemented by modern disciplines such as meteorology and oceanography – can provide valuable insights in areas where archaeological

methods are not so revealing. Historical accounts of maritime journeys, trade practices, and military campaigns can shed light, for example, on the seasonality of maritime life surrounding archaeological sites and landscapes, such as ports and maritime routes.

The relationship between maritime archaeology and art history is a complex one. Shipwrecks can, as with the example of the Belitung ship, be the very places where whole, pristine, and excellent examples of Islamic decorative art of the kind favored by art historians are preserved for centuries. But, as in the case of Belitung, it is also from such submerged locations that artifacts attracting aesthetic appreciation can be extracted and traded for profit. Nevertheless, submerged Islamic sites do offer the prospect of preserving a wider range of artifacts, given the often better preservation of organic materials in low-oxygen environments, than those attracting the attention of art historians. Thus, maritime archaeology has the potential to contribute its own perspective on long-distance contacts enjoyed by Muslim societies, on the ordinary lives of seafaring Muslims, and on the material culture of Muslims that art-historical inquiries do not.

Both maritime and Islamic archaeologists have in the past faced a struggle to win respect for their work as either methodologically rigorous or legitimate forms of archaeological inquiry and to shake off associations with emphatically non-archaeological practices such as treasure hunting. The non-archaeological recovery of items from underwater for profit has a long history worldwide. In some Islamic-world locations, colonial exploitation and postcolonial institutional weakness have increased the problems of non-archaeological extraction. Controversy over treasure hunting has already erupted: Seabed Explorations broke no Indonesian laws when it worked under license on the Belitung wreck. But the high-prestige ceramics it brought to the surface were subsequently sold to the Singapore government for $32 million, and no comprehensive archaeological record of the excavations was published: In 2011, the Smithsonian Institute shelved plans to hold an exhibition of finds from the wreck after vociferous objections to a show based on traded heritage.

Future Directions

For many maritime archaeologists working on the Islamic world, the key to overcoming problems of treasure hunting is institutional capacity building. A new Centre for Maritime Archaeology was established in 2009 at the University of Alexandria, Egypt; it is the first in an Arab country. Efforts are under way to establish capacity and extend education elsewhere in the Islamic world, particularly the Gulf.

Maritime archaeological inquiry in the Islamic world is often limited, and enabled, by the availability of resources and the disposition of funding bodies. Future investigation there is likely to be sporadic, with issues of political stability, international diplomacy, national priority, and funding likely to skew activity towards countries, such as those in the Gulf, with the resources, institutional capacity, and inclination to support archaeological work.

Any archaeological investigation of Islamic subjects cannot hope to remain outside contemporary politics. On a practical level, political and security issues impinge on the ability of maritime archaeologists to access sites for investigation. On a theoretical level, the often hegemonic ideologies of Orientalists, religious conservatives, and secular nationalists, constructing insular notions of the Islamic or national past, stand to be challenged by the findings of archaeology, not least that found underwater, as well as in ancient maritime trading settlements.

Islamic Archaeology

Andrew Petersen
School of Archaeology, History and Anthropology, University of Wales Trinity Saint David, Ceredigion, UK

Introduction

Islamic archaeology is concerned with the investigation of the material culture and historical record of Muslim peoples and societies. As an area of academic inquiry and as a practical part of heritage management, Islamic archaeology is growing as the role of Islam in the world increases both as a political force and in terms of its financial resources. There are a number of conceptual difficulties with the term "Islamic archaeology" which will be discussed below, but for the present it is used in broad inclusive fashion to encompass any archaeology where Islam is a significant factor in the history or heritage of the region or theme

under consideration. It will be clear that just as the Islamic world covers a large area and a significant proportion of the world's land surface, so the archaeology of Islam will incorporate considerable diversity in terms of ethnicities, beliefs, environments, languages, histories, politics, and economics. One of the problems or tensions within this area of inquiry is the reconciliation of such diversity and the question of the coherence of the subject as a whole.

Definition

As an academic field of inquiry, Islamic archaeology can be interpreted in many ways from an archaeology narrow focus on the religion of Islam to a much broader investigation of the material culture of societies where a significant proportion of the population was Muslim. In some cases the term may even be extended to non-Muslim societies where there was either a Muslim minority or significant interaction with the Muslim world. At this point it might be worth comparing Islamic archaeology to Christian or Hindu archaeology where the focus of research is firmly on the religious aspect of those societies, whereas other aspects of these societies (trade, economy, conflict) may be outside the remit of the study. Islamic archaeology is generally construed to have a wider remit partly because the religion of Islam is a structuring principle for all aspects of a society and individual's life. Thus, trade, politics, warfare, and social relations are all within the scope of Muslim religious life. Secondly from its inception in the nineteenth century, Islamic archaeology has not placed particular emphasis on Islam as a religion and has used the adjective "Islamic" as a general term to refer to cultures where Islam was the dominant religion.

The term "Islamic Archaeology" was first used in the late nineteenth century to refer to the investigation of archaeological sites where the material remains of predominantly Muslim settlements were excavated and objects retrieved for display in museums or private collections. Medieval Islamic remains were intimately linked with the present, and in the nineteenth and early twentieth centuries, there was often a tendency to see Muslim society as either static or in an inexorable decline. There was therefore little to be gained from an archaeological study of Muslim society as the trajectory of development was already known, and the only value that could be derived was from the excavation and retrieval of decorative objects. During the twentieth century the meaning of the term shifted away from the concept of object retrieval to the idea of archaeology as a means of understanding past societies. In many ways this change mirrors developments elsewhere in archaeology. However, because Islamic archaeology was overwhelmingly carried out by outsiders from Europe or America, the change from acquisition of objects to understanding of the development of societies was intimately linked to ideas of Orientalism as defined by the renowned Palestinian Egyptian scholar Edward Said (1978). While excavating objects and removing them to a distant location may be interpreted as a refined form of theft, the collection of information to construct narratives could be seen as part of a colonial/Orientalist attempt to appropriate the past history of peoples seen as somehow inferior. In this case archaeology was a method of control and according to Said an integral part of the colonial apparatus. Of course this does not apply exclusively to Islamic archaeology, and in the scheme of things, Islamic archaeology had a relatively minor role in relation to Egyptology, Assyriology, and Biblical Archaeology. It should also be noted that a crucial component of the archaeology of many of these pre-Islamic civilizations was a conscious effort to disassociate the glorious ancient civilizations from contemporary Muslim cultures.

Historical Background

Islamic archaeology may be divided into two distinct phases: (1) the late nineteenth and early twentieth century and (2) the second half of the twentieth century up to the present day. The first phase is characterized by European colonialism, a

preoccupation with major urban sites and a Middle Eastern focus. The second phase is characterized by differing national agendas, a shift toward regional survey and widening geographical focus beyond the boundaries of the Middle East.

1880–1945

Although Islamic remains had been found in Middle Eastern excavations of ancient sites during the early and mid-nineteenth century, they were not the objective of these projects and were generally either discarded or ignored. The specific targeting of Islamic-period sites and remains began in the latter part of the nineteenth century and was part of a growing interest in the development of art and architecture. The term "Islamic archaeology" did not occur until the 1890s when the concept of Islamic civilization was first adopted as a term to describe the culture and history of Muslim peoples. The philosophy behind the use of the term "Islamic" derived from the ideas of Auguste Comte and William Robertson who viewed religion from a comparative cultural and secular perspective rather than as a matter of faith and spirituality. The first use of this terminology in relation to material culture was the 1893 exhibition of Islamic antiquities in Paris which had the title "Exposition d'Art Musulman" (Exhibition of Islamic Art) rather than more usual terms of Persian or Arab art (Vernoit 1997). The new terminology was rapidly adopted, and the first excavations to be carried out as Islamic archaeology occurred in diverse locations such as Qal'a Bani Hammad in Algeria and Samarqand in the newly annexed Russian provinces of Central Asia. In both of these cases, the excavations were linked to colonial expansion and an attempt to create heritage and histories which would support European domination. Even the excavation of the Spanish Umayyad site of Madinat al-Zahra in 1910 has been linked to that country's colonial ambitions in Morocco which was made a joint French/Spanish protectorate in 1912. The same colonial interest is less evident in the German excavations at the ninth-century site of Samarra in Iraq during the years immediately preceding the First World War. As capital of the Abbasid state and the world's largest recognized archaeological site (45 km N-S), Samarra was a fitting setting for one of the first major scientific excavations of an Islamic site. Unfortunately the excavation and survey work was curtailed by the First World War; however, the results of this fieldwork are still being analyzed and continue to produce important new information (Northedge 2008). Samarra was particularly significant because it was regarded as the earliest expression of many features which were later considered to be characteristic of Islamic art including the three types of stucco decoration (carved, bevelled, and molded) and several distinct pottery types including cobalt blue-painted white ware and lusterware.

Following the collapse of the Ottoman Empire at the end of the First World War and the signing of the Sykes-Picot Agreement, large areas of the Middle East and North Africa came under European control pending eventual independence. During this period excavations at Islamic sites were seen as a way of connecting people with their own national histories and as a way of training local archaeologists. For example, the Iraqi archaeologist Fuad Safar excavated the early eighth-century Umayyad city of Wasit in southern Iraq between 1936 and 1942. In Palestine Dimitri Baramki working for the Department of Antiquities of Palestine excavated the eight-century Umayyad palace at Khirbat al-Mafjar between 1938 and 1942. The principal building at Khirbat al-Mafjar was a monumental bathhouse with magnificent mosaic decoration and sculptures (Hamilton 1959, 1988). The most surprising feature of the decoration was the presence of figural sculptures of semi-nude women which adorned the wall of the bathhouse. Although similar figures had been found as paintings in the bathhouse at Qusayr 'Amra in Jordan, the most unusual aspect of the Khirbat al-Mafjar figures is that they were three-dimensional statues – a form of artistic creation which was generally regarded as forbidden within Islam.

At this point it is worth mentioning the role of architectural survey within the growing field of Islamic archaeology (Fig. 1). For many centuries

Islamic Archaeology, Fig. 1 Khan al-Idham in Ramla, Israel. This medieval khan or caravanserai was probably built in the fourteenth century and was later reused as a pottery factory. The photograph taken in the early twentieth century shows recently made jars being allowed to dry prior to firing

the architecture of the Islamic world had been admired and studied by Europeans, and it is known that there was considerable interchange of architectural ideas during the period of the Crusades. However, the recording and measurement of Muslim buildings as ancient monuments did not start until the late nineteenth century and was motivated by the same concerns which saw the excavation of Islamic sites. One of the earliest buildings to be documented was the early eighth-century Umayyad bathhouse at Qusayr ‘Amra discovered and recorded by the Czech anthropologist Alois Musil in 1908. The site is chiefly famous for its frescoes which include the earliest depiction of the night sky painted inside a dome. The architecture of the bathhouse in Qusayr ‘Amra is relatively modest when compared to the immense fortified palatial structure of Al-Ukhaidir first recorded by Gertrude Bell in 1909 and later published as monograph under the title *Palace and Mosque at Ukhaidir* (Bell 1914). As a British aristocrat and later administrator for the newly created state of Iraq, Gertrude Bell was firmly in the Orientalist tradition of archaeologists. However, the most famous historian of Islamic architecture and one of the most important figures in Islamic archaeology K.A.C. Creswell was not from such a privileged background and always remained slightly apart from the colonial establishment. Creswell started his work in the field by writing reports on Islamic architecture for the Palestine Mandatory Government in the years following the end of the First World War. He later developed as an independent scholar through a commission to write an account of Islamic architecture in Egypt and ultimately became Professor of Islamic Archaeology at the American University in Cairo (Grabar 1991). Creswell’s achievement was to establish a firm chronological base for the development of Islamic architecture and to pioneer a systematic empirical method of recording more akin to archaeology than art history (Creswell 1932, 1940, 1952, 1959).

It will be apparent that most of the interest and fieldwork in Islamic archaeology during the early twentieth century was concerned with the first three centuries of Muslim rule and that remains from the medieval period to later were seldom investigated. Jean Sauvaget was one of the first scholars to investigate medieval and later Islamic remains with his work on Damascus (1932) and Aleppo (1941). Sauvaget’s approach was markedly different from Creswell’s relying on historical documents, inscriptions, and a profound knowledge of local topography rather than meticulous measurements. Another scholar who made a major contribution to the archaeology of both the medieval and early Islamic periods was the Swiss

Orientalist Max van Berchem (1863–1921). Van Berchem's primary expertise was recording, translating, and analyzing Arabic inscriptions although he was careful to see them in context and often made a full study of the monument in which they occurred (see, e.g., Van Berchem 2001). Van Berchem's legacy continues both in his publications and in the Fondation Max van Berchem created in 1973.

1945–The Present

The Second World War marked a shift in the political makeup of the Middle East and North Africa which had a profound impact on archaeology. The European-dominated colonial and mandatory regimes were gradually replaced by independent though rarely democratic governments. The new governments were interested in developing their national identities, and archaeology was increasingly used to support these agendas. Although nationalist presentations of archaeology do not generally appear in academic accounts of excavations, the presentation of sites in popular literature and heritage may be used to re-enforce perceptions of national identity. For example, in Iraq Samarra was used by the Saddam regime to portray the glories of Iraqi civilization, while in Jordan the Umayyad desert castles were used to reenforce the nation's Arab identity. Despite these nationalist agendas foreign (European, American, and latterly Japanese) teams were still permitted to work in these countries; these projects had to be in collaboration with archaeologists from the countries concerned. Such regulations led to an increasing internationalization of Islamic archaeology with sharing of skills and resources.

One of the most important joint projects was the excavation of the Iranian coastal city of Siraf by the British Institute of Persian Studies and the Iranian Archaeological Service (Whitehouse 1970). The city which flourished between the mid-eighth and early twelfth century was important as a major city and one of the principal ports on the Arabian/Persian Gulf. Beyond its immediate findings in relation to the city and port, the Siraf project was important for Islamic archaeology as a whole. In the first place the large-scale excavations were important for the quantity of ceramic finds which overlapped with those of Samarra. Because Samarran pottery was encountered in many places, the Siraf finds were able to provide a corrective to the dating of many of these wares (Mason and Keal 1991). Secondly the Siraf project drew attention to the Indian Ocean trade of which it formed a central part with ceramics from the Gulf region found as far afield as Japan and South Africa.

The Indian Ocean connection is an aspect of Islamic archaeology that has seen increasing interest in the latter part of the twentieth century with excavations in places such as Pakistan (Banbhore), Sri Lanka (Mantai), and East Africa (Kilwa, Mantai, and Shanga). The geographical scope of Islamic archaeology was further increased from 1992 when the collapse of the Soviet Union opened much of Central Asia and the Caucasus to international teams. Although Soviet (and previously Imperial Russian) teams had been working on Islamic sites from the late nineteenth century, the results of this work were not well known internationally partly because of language problems and also for ideological reasons. Significant initiatives in this area include the International Merv Project focussing on the eastern capital of the Abbasid caliphate. In addition to the direct results of excavations, such projects also encourage and enable the translation and wider dissemination of information about the archaeology of the region. Other regions outside the traditional areas of research that have seen archaeological projects focussed on Islamic remains include West Africa (Timbuktu, Gao, and Tadmeka) (Insoll 2003), South East Asia (Lape 2005), and even Australia where evidence has been found of seventeenth-century Indonesian Muslim fishermen (Russell 2004).

In addition to an expansion in the geographical range of Islamic archaeology, there has also been an increase in the range of techniques used with an increasing emphasis on regional survey. One of the first regional survey projects which incorporated the Islamic period was Robert Adams' survey of the Diyala basin which used regional survey to investigate rural and urban settlement

patterns in the vicinity of Baghdad (Adams 1965). Regional surveys are by their nature multi-period and interdisciplinary and have been instrumental in setting Islamic sites within their wider environmental and chronological context. Regional survey has also led to a greater interest in rural sites throughout the Middle East and North Africa (see, e.g., De Meulemeester's 2005 article on granaries in Morocco and Iberia; Figs. 2 and 3). One of the largest rural excavations was the Khirbat

Islamic Archaeology, Fig. 2 Date-palm garden and fortified residence at Umm Salal Muhammad in Qatar. Date palms have a long association with Islamic culture and are often used to shelter other crops

Islamic Archaeology, Fig. 3 Twelfth- to thirteenth-century stone water-jar stand from Egypt or Syria. Water is extremely important in Islamic culture and was used as a decorative feature in gardens, mosques, and houses

Faris project in Jordan which took place between 1988 and 1994 (McQuitty and Falkner 1993). The excavation of this small village revealed more than 1,000 years of Islamic occupation, and the publication of this site will be a major contribution to our understanding of a typical rural village economy.

Current Debates

A number of theoretical concerns can be identified within Islamic archaeology which can be placed into three main categories: religious concerns, questions of scope, and the relationship with art history.

Religious concerns are focussed on the characterization of archaeology as "Islamic." While this question is discussed more fully in the entry on the Archaeology of the Islamic Religion, it is important to outline the main areas of contention which include (1) whether the excavation of Islamic sites should be restricted to Muslims; (2) whether Islamic archaeology should concern itself with the excavation of pre-Islamic remains pertinent to the origins of the religion; (3) in what circumstances and by whom a Muslim grave can be excavated; and (4) what role practitioners of Islamic archaeology should have in promoting intercultural understanding.

Practical problems include the definition of the scope of Islamic archaeology. While there is a general acceptance that remains from the early Islamic period in Saudi Arabia, Syria, or Jordan can be included within this field of inquiry, how far can this term be applied? For example, is it legitimate to use the term to describe excavation of an eighteenth-century Ottoman village in the Balkans? Similarly can the term "Islamic" be applied to industrial remains or the investigation of recent material culture? With increasing levels of globalization from the sixteenth century onward, different terms may be more appropriate to convey complex interactions between different societies and religions.

Islamic archaeology is unusual because art history had a formative influence on the development of the subject. Many of the first archaeological excavations of Islamic remains were organized to retrieve objects of aesthetic interest to collectors and museums. Because of this art history has continued to have considerable influence over the development of Islamic archaeology despite having very different aims and methodologies (Canby 2000). In some cases this has led to problems; thus, art-historical approaches have led to

Islamic Archaeology, Fig. 4 Fourteenth-century fritware ceramic cenotaph (grave marker) from Central Asia. In addition to vessels many objects in the Islamic world were made of ceramic material including mihrab niches, grave markers, and wall decoration

concentration of interest on glazed ceramics to the detriment of studies of coarse wares which have always made up the bulk of material on archaeological sites (Fig. 4). Similarly art historians have tended to focus on high-status buildings such as palaces, mosques, and mausolea, while ordinary housing and small village shrines have been barely noticed.

International Perspectives

By definition Islamic archaeology has an international perspective with the field of study encompassing much of Asia, Africa, and parts of Europe. Each country has its own approach to Islamic remains influenced by political, cultural, and religious factors. There are, for example, some European countries such as Spain and Portugal which were once major centers of Muslim civilization but are now overwhelmingly Christian or secular in outlook. For many years there was a negative attitude toward the Islamic history in these countries resulting both from colonial encounters and internal politics. However, recently there has been a willingness to accommodate and celebrate the Muslim heritage of both Spain (Borrás Gualís et al. 2000; De Meulemeester 2005) and Portugal (Torres and Macias 2001) seen in the publications of the organization *Museum With No Frontiers*. In other Christian countries, however, the situation is not so positive; thus, there has been very little attempt to investigate the Islamic archaeology of Malta despite a rich and deep Islamic heritage.

In Israel the situation is more complex partly because of the contested nature of the international borders, and also because even within Israel, there is a sizeable Muslim population. As a state Israel sees Jewish heritage and culture as predominant and has been reluctant to recognize any Palestinian (Christian or Muslim) culture as important. However, Israel also has a very positive approach to archaeology which has meant that there have been a number of excavations of important Muslim sites as well as numerous contract excavations of smaller sites (Petersen 2005). In Saudi Arabia the situation is reversed with a great deal of support for Islamic heritage and culture yet a lingering suspicion of archaeology.

Future Directions

Archaeology is becoming more important in Muslim countries partly as a way of developing tourism and partly because people may feel more interest in the development of their own culture and religion than in the distant past. It is, for example, notable that the Gulf states are now investing in archaeology as a way of reenforcing a sense of identity and heritage which is challenged by the rapid urbanization and development of these countries. It is likely that in the future these countries may well lead the way in supporting and developing Islamic archaeology not only in their own countries but further afield in Muslim countries with fewer resources.

The Balkan wars of the 1990s demonstrate how the presence of Muslims in Europe can still cause controversy. More recently controversies over the depiction of Islam by right-wing radicals have ignited debates about the integration of Islam into European society. While archaeology may generally be seen as remote from these debates, it can play a part in demonstrating the longevity of the relationship between Europe and Islam. Moreover, archaeology can shift the focus from violent interactions such as the Crusades to the more peaceful interactions such as trade and cultural exchange (see, e.g., Petersen 2008).

It is noticeable that during the twentieth century the majority of Islamic archaeology projects and excavations were focussed on the early Islamic (631–1000) and medieval (1000–1500) periods. However, recently there has been a growing interest in the post-medieval period influenced by the theories and concerns of historical archaeology. It is likely that this interest will develop particularly as it helps our understanding of the relationship of Islamic society with the rest of the world.

Islamic Archaeology and Art History

Leslee Katrina Michelsen
Curatorial Department, Museum of Islamic Art, Doha, Qatar

Introduction

The discipline of Islamic art history is connected inextricably with that of archaeology, for reasons of both history and philosophy. Each field of study examines the material culture of the Islamic world and utilizes many of the same sources, particularly in the premodern period.

The principal methodologies of the fields differ in their approaches to the objects, with archaeology – in principle – privileging all materials equally and being concerned primarily with the relationships between and among excavated objects, while art history has an overriding interest in the objects themselves.

Yet although art history is primarily concerned with form and content, it is certainly and deeply informed by context. The increasing emphasis in the discipline on visual culture has resulted in greater attention to, and emphasis on, the cultural milieux in which the objects were produced.

Key Issues

The nature of Islamic art history is connected intimately with the physical situations of available objects. The relative lack of grave goods in Islamic burials, combined with the deposition of "masterpieces" in numerous shrines and treasuries, provided a wealth of extant, unburied artifacts that in many cases became the original materials for Islamic art history in its infancy as a discipline. Some of the most celebrated examples of such objects include the Shroud of Saint Josse (Fig. 1) and the Pisa Griffin (Fig. 2), both of which have been in European hands since the medieval era and the subjects of myriad studies.

On the other hand, the widespread practice of the commercial excavation of Islamic sites, as well as academic investigations, provided a supply of material culture for museums and universities that formed the basis of numerous canonical collections. (Regrettably, this also included wide-scale looting of sites and trafficking in illicit antiquities – practices that are, shamefully, ongoing today).

Certainly the plethora of portable arts – ceramics, stucco, metalwork, etc. – found in archaeological contexts informed their increasing inclusion into the field of Islamic art history and even their "legitimization" as objects of serious study. A series of catalogues devoted to

exhaustive collections – private or public – of specific media have been very commonly cited and useful reference works in the field (Ettinghausen 1962; Baer 1983; Grube 1994).

The practice of "collecting history" of the Islamic world reached a climax in the late nineteenth and early twentieth century, when a combination of factors – including a number of excavations of Islamic sites – provided a wealth of materials for the archaeologist and the art historian. In many ways the studies of this period were quite similar across the two disciplines, with scholars in both fields devoting more attention to the more aesthetically pleasing objects for purposes of initial collection as well as later study and display. One such example is the Metropolitan Museum of Art's excavations at Nishapur in the 1930s and 1940s, in which the oft-cited, and indisputably useful, tome on pottery nonetheless represents only a small portion of the ceramics at the site (Wilkinson 1973). The "best" of these were selected for initial collection, as well as later publication, study, and exhibition (Fig. 3).

Certainly pottery, perhaps more than any other medium, has benefitted from its common and widespread availability in archaeological settings as well as its treatment in art-historical studies. Forms and fabrics have long been included as part of standard descriptions of ceramics in art-historical texts, and collaborations between and among colleagues in art history and archaeology have resulted in intriguing new observations on both forms and functions (Golombek et al. 1996).

Additionally, examinations of standing as well as excavated architecture and its decoration contributed significantly to the formation of the field. Both Qusayr ʿAmra (Fig. 4), which was not excavated, and Khirbat al-Mafjar, which was (and continues to be), provide important information to the archaeologist as well as the art historian on Umayyad art and architecture, including patronage, audience, and memory. Both structures were initially examined via, and restricted to, a "sub-antique" designation, which has only been corrected with recent and careful scholarship (see Fowden 2004) – treatments that are at the

Islamic Archaeology and Art History, Fig. 4 Qusayr ʿAmra, eighth century CE, Jordan. (UNESCO World Heritage Centre)

forefront of reexaminations of the canon of Islamic art history.

This closely knitted history between Islamic archaeology and art history has resulted in a great privileging of the early centuries of Islamic art, as Grabar noted in his observations on the field: "The concentration of scholarly effort on the early centuries of Islam, with its concomitant emphasis on the Arab world, reflects in part the earlier concern of scholarship with unraveling and explaining the beginnings of Islamic culture and in part the influence of archaeology, a technique far more at ease with early monuments than with recent ones" (Grabar 1983: 7). Current emphasis is redressing this imbalance, with attempts to pay greater attention to later centuries and less-studied sites and their material culture (Vernoit 2000; Komaroff 2000).

Current Debates

Islamic art history has been concerned with the cultural setting surrounding and necessitating the production of visual culture for many years. In the 1950s the eminent Islamic art historian Richard Ettinghausen reminded his colleagues that: "We have to study the monument's function, or the object's use, the conditions of life, work and trade under which it was made, and all the associations that helped to create the work, whether they were derived from religious, magical, astrological, literary or folkloristic concepts" (Ettinghausen 1951).

This is perhaps too little known outside the field of art history, with frequent assumptions that there is an over-reliance on aesthetics and connoisseurship at the heart of the discipline. Yet visual culture certainly has a materiality to it, recognized in the study and practice of art history and with a meaning both in and across time. Therefore a shift to the examination of material culture in art history – with visual culture as one part of a greater cultural world – prioritizes the place of art, but definitively within its cultural setting.

Additionally, certain characteristics of Islamic society – including the collecting of calligraphy, the commissioning of fine buildings that are palpably different from mere shelters, or championing a series of objects made in precious substances or imitating those substances – are clearly art-historical aspects of material culture, at least in part, and therefore bear examining under that lens.

Future Directions

Both formalism and contextualism have significant roles to play in art history, and in the field of Islamic art history, this has great importance for

the role that museums, in particular, play in presenting and interpreting the material and visual cultural of the Islamic world to the public. The term "Islamic" can be problematic, encompassing as it does a wide range of explicitly secular works produced by and for a variety of peoples of disparate faiths (Grabar 1973). One very recent development is the decision by the Metropolitan Museum of Art to reject the designation of "Islamic Art" for its renovated galleries in favor of geographic designations.

In recent years a number of significant collections of Islamic art have been inaugurated or reorganized, reopening the questions surrounding the choices made in collecting and displaying Islamic art. These are even more charged in the current political climate, creating a greater role but also much greater responsibility, for the Islamic art historian.

Additionally, the expansion of Islamic art history to incorporate lesser-studied elements of the Islamic world – whether by media, temporality, or geographic location – has led, rather unsurprisingly, to a greater specialization among Islamic art historians. In the course of one or two generations of scholars, an "inclusive" expert on topics as wide-ranging as Nasrid ceramics to contemporary Turkish architecture has been steadily replaced, for reasons of the rapidly growing depth and breadth of the field, by scholars increasingly focused on a narrower range of media, times, and places.

It therefore seems logical that at some point in the near future, the overemphasis on the early centuries of Islam, and its heavy reliance on archaeology, may be lessened or even superseded. While unfortunate, it would also point to the great strength of the partnership between Islamic archaeology and art history that created the foundations for such exponential growth and development.

Islamic Industry, Archaeology of

Rebecca Bridgman
Islamic and South Asian Art, Birmingham Museums Trust, Birmingham, UK

Introduction

Industry in the medieval and post-medieval Islamic world was most commonly associated with urban environments, where it was predominantly organized and specialized in nature.

Production sites, in locations from Baŷŷāna, southeast Iberia (Acién Almansa et al. 1990); al-Basra, North Africa (Benco 1987; Benco et al. 2002; Robertshaw et al. 2010); Raqqa on the Euphrates (Henderson et al. 2004: 440–441) to Merv, Central Asia (Herrmann et al. 1997: 10–13), provide examples of industrial complexes. Such sites are key to our understanding of industry; however, the range of goods they produced, found on a greater number of consumption sites, also provide vital evidence of manufacturing. This entry will examine industrial production from the standpoint of artifacts, with evidence drawn from a range of contexts, predominantly medieval in date, in which those objects were made and used.

Definition

An industry is identified either by the presence of the site of manufacture, such as a kiln, or by a groups of artifacts, sometimes spread over a wide geographical area, that adhere to a particular morphology or technological style. Ceramics are the most intensively studied industrial product from most archaeological contexts and, along with metal and glass objects, represent the most common range of artifacts recovered during archaeological investigation. Both artifacts recovered from excavations and those held in museum collections as examples of Islamic art can shed light on key issues pertaining to industry. These include, for metal, the complexity and level of organization of production; for glass, the important technological change in production; and for ceramics, the vast range of types and the diffusion of styles. Exploration of these issues will allow consideration of how patterns of production and distribution of those artifacts can inform our understanding of industry. The focus of this discussion, owing to the length of this entry, will be Iberia, the Mediterranean, and the central Islamic lands.

Historical Background

Sināʿa, or the occupation of and production by artisans, was strictly governed by *hisba*, a set of moral codes often written in manuals, which were particularly associated with markets and enforced by an official known as a *muhtasib* (Milwright 2010: 143–144). *Hisba* documents provide key dated records of market conditions and the organization of industry. Both archaeological and historical evidence indicate, however, that the guidelines given in *hisba* documents were not always strictly adhered to. Excavation of urban settlements provides evidence that polluting industry was not always located away from centers of population, for example. During the early Islamic period, in the Syrian cities of Jarash and Baysan, ceramic kilns were located close to the urban center (Walmsley 2007: 117–119). Evolution in the organization of industry can be indicated by historical documents. By the fifteenth and sixteenth centuries CE, for example, court documents indicate that the role of the *muhtasib* was in decline, as many of its functions were supplanted by newly emerging guild structures that grouped and organized pre-existing craft associations (Hama 2008).

The Geniza documents provide arguably the best source of information on the organization of industry, albeit limited to the Mediterranean region. They indicate that the division of labor resulted in craftsmen specialized in industries ranging from the production of kohl sticks to house mats (Goitein 2003: 33–48). It was the textile industry, however, which represented the most significant production (Ashtor 1976: 95–97) but one which is rarely evidenced in the archaeological record, as such organic artifacts only survive in contexts where conditions permit their preservation. Even without the presence of textiles, production can sometimes be identified archaeologically, through tools such as loom weights, as at Baŷŷāna (Acién Almansa et al. 1990: 156). Important textile production centers such as Tinnīs, where fabrics embroidered with honorific titles referred to as *tirāz* were produced, provide examples of manufactories which served and were controlled by ruling authorities (Ashtor 1976: 150–152). Records from the Ottoman court, dating to the late fifteenth and sixteenth century CE, provide another example of impetus from the ruling classes which lead to industrial-scale production, here associated with products such as

Iznik pottery. Iznik products, in common with *tirāz* fabrics, were also consumed beyond courtly circles, as evidenced most strongly by their patterns of distribution (Atasoy and Raby 1989: 264–268; Barker 1995: 52–63).

Most recently, studies of an Arabic dictionary of crafts, written in Damascus between 1890 and 1905, have provided detailed textual accounts of a total of 437 artisanal activities, from pottery production to blacksmithing (Milwright 2011). Relating to the medieval period, treatises are amongst the documents that provide details of the processes of industrial production. For example, texts written by al-Kindī during the ninth century CE describe steel and iron manufacture, particularly in relation to swords (Allan 1979: 85–86), at centers including Merv (Herrmann et al. 1997: 12). For the early fourteenth century CE, a treatise by Abu al-Qasim of Kashan provides key information on the production of highly decorated pottery, such as lustre wares (see below). Here the recipe for ceramic "stonepaste" bodies is described as comprising ten parts quartz, one part crushed glass, and one part white clay (Watson 2004: 24–26). Texts on the objects themselves are another important source of evidence. For example artifacts such as inlaid brass objects, often in museum collections and classified as Islamic art, can provide evidence of the place and date of manufacture, sometimes in conjunction with a named patron or even artist (see Figs. 1 and 2). It is through such evidence that the diffusion of style and designs on inlaid brass objects has, in part, been defined. As a result, late twelfth-century CE Herat has been identified as the point of origin (within the Islamic world) of inlaying on brass before transmission to Mosul and then on to a number of centers, most notably Si'irt or Konya, Damascus, Cairo, and Fars (Ward 1993: 71–93).

On ceramics, inscriptions have allowed some of the best examples of lustre and polychrome *mina'i* pottery, produced in Kashan during the late twelfth and early thirteenth centuries CE, to be associated with a craftsman called Abu Zaid (Watson 2004: 55). However, it should be noted that a single name or signature may in fact refer to a workshop, or group of workshops, rather than an individual, as has been suggested for ceramics

Islamic Industry, Archaeology of, Fig. 1 Brass casket (O.2–1908), inlaid with gold and silver with a later copper and brass rim strip and iron clasp, 1366–1368 CE, probably made in Cairo. Given by the Rev. T. Hewitt, 1908.© The Fitzwilliam Museum, Cambridge

Islamic Industry, Archaeology of, Fig. 2 Detail of brass casket (O.2–1908) inlaid with the name of the patron, who was a secretary in the Mamluk government. Given by the Rev. T. Hewitt, 1908.© The Fitzwilliam Museum, Cambridge

(Milwright 1999: 507). The name or symbol of the patron can lead to association with a specific location. For example, an enamelled mosque lamp

from the collection at The Fitzwilliam Museum bears the name of its patron, the Mamluk Amir Shaykhu al-Nasīrī (Fig. 3). This object was almost certainly produced for his mosque complex in Cairo, which was completed between 1349 and 1356 CE (Fitzwilliam Museum 2005: 129). The following sections will consider predominantly archaeological artifacts recovered from known contexts but with reference to museum objects to explore key issues relating to their manufacture.

Key Issues

Metalworking

The range of materials used, the complexity of their extraction, and the vast array of techniques employed to produce finished objects make metal artifacts one of the most complex object types produced on an industrial scale in the Islamic world. With the exception of copper, metals produced were predominantly alloys, made from more than one raw material.

Brass (an alloy of copper and zinc) was one of the most popular metals employed to produce utilitarian and decorative objects, using techniques from casting to sheet working (for the latter, see Ward 1993: 30–34). These objects reached their most spectacular form from the late twelfth to fifteenth century CE, when increasing numbers of brass objects were produced with inlaid designs using metals of contrasting color, such as silver and gold (Ward 1993: 71–121; for an example, see Figs. 1 and 2). Copper (with very low levels of alloying components such as zinc, lead, and tin) was also used to produce utilitarian objects, such as cooking pots and buckets, but these vessels may be under-represented in many archaeological assemblages, as when broken, they were probably recycled (Ponting 2008: 55). Similarly, only rare examples of precious metals survive probably because of their intrinsic and re-melting value, although rare finds from hoards including Nahavand and Harari provide evidence of Central Asian production from the late tenth to twelfth centuries CE (Allan 1982: 14–16). Ternary alloys with varying quantities of copper, zinc, lead, or tin were also used to produce largely utilitarian cast objects, while iron, sometimes alloyed with carbon to produce steel, was often used to make bladed objects from household scissors and knives to weaponry and armor (Allan 1979: 52, 66–82).

The raw materials to produce these metals were obtained through both open-cast and underground mining, which took place on an industrial scale, sometimes requiring ventilation shafts and drainage devices (Al-Hassan and Hill 1986: 235–244). Given that copper was a key ingredient in the production of the most commonly occurring metal objects (see above), it is perhaps not surprising that there is considerable evidence for the extraction of copper. For example, significant copper mines, smelting sites, and other industrial activities dating to the early Islamic period have

been identified in the Timna Valley, in the rural hinterland of Ayla, as evidenced by underground galleries measuring up to 3 km length and extensive slag deposits (Walmsley 2007: 119–120).

The transformation of mined ores into finished objects was a complex process, which often occurred at two or more locations, sometimes with considerable distance between the source of raw material and the workshop where the final product was manufactured. At Saltés, an island at the confluence of three rivers close to Huelva in the southern Iberian Peninsula, polymetallic minerals were processed into bars of metal, following transport from relatively distant sources in the Sierra Morena Mountains (Bazzana and Trauth 2008). Once processed at sites such as Marandet or Saltés, metals could be exported to workshops elsewhere, where they were fashioned into objects. At Merv, for example, a workshop dating to the ninth or tenth centuries CE produced steel in refractory crucibles by fusing non-local supplies of iron (Herrmann and Kurbansakhatov 1994: 70; see Fig. 4). The resulting steel was doubtless used to produce the weaponry for which the settlement was famed (Herrmann et al. 1997: 12). At Tiberias, a Fatimid-period metalwork shop similarly employed non-local resources. The presence of that workshop is witnessed most prominently by a significant hoard, which included a range of artifacts (from lamp stands to bowls), made in a variety of metal types (copper, brass, high-tin bronze, and ternary alloys), as well as 200 kg of scrap metal, predominantly copper, in the form of broken objects, lathe turnings, and folded packets (Ponting 2008). This metalwork shop probably carried out limited casting of base metals but clearly focused on the repair of brass and ternary alloy objects and the collection of scrap copper, possibly for recycling through re-melting at another location (Ponting 2008: 59–60). Although this pattern of production of metal objects can readily be identified, it should be noted that there is also evidence of variation. Al-Basra provides just one example of a site at which, during the ninth to twelfth centuries CE, a full range of metalworking, from smelting of raw materials to the production of finished objects, took place at a single location (Benco et al. 2002).

Islamic Industry, Archaeology of, Fig. 4 Crucible used to produce metals at Merv. (Published with kind permission of Ann Feuerbach)

As evidenced by the processes described here, the production of metal objects necessitated high levels of organization and considerable specialist expertise. Developing an understanding of those processes of production is relevant to other object types, in particular glass, which could also be produced in multiple stages and locations, as well as being re-melted following initial production or the breakage of objects.

Glass

Silica (often either quartz pebbles or coastal sands) along with a soda flux (either natron or plant ash) and lime (calcium oxide, present either in shell fragments or plant ash) can be combined, through heating, to form glass (for the methods and range of production, see Henderson 2013). As with other forms of material culture, decisions involved in the manufacture of glass objects, from the selection of different types of raw material to methods of decoration, form part of the *chaîne opératoire* of production reflecting not only industrial processes and availability of materials but also the society in which they are made. Soda-lime-silica glasses predominate in the medieval Islamic world, although lead could also be added, probably to make softer material that could

be cut or ground (Carboni and Whitehouse 2001: 28). Raw glass could then be blown or molded and decorated with a plethora of techniques from filling and scratching to enamelling and gilding (for discussion of working and decorating techniques, see Carboni and Whitehouse 2001).

The evolution in technology, which occurred between the ninth and eleventh centuries CE in the eastern Mediterranean, is the most important issue that has emerged recently in relation to industrial production of glass. During that time, the type of soda flux and as a result the source of silica used in glass production underwent a significant period of change and experimentation. Around the ninth century CE, the mineral natron, long used as a flux in glass production in the Levant and Egypt, began to be replaced with plant ash from halophytic plants that grow in coastal, salt marsh, or desert areas, using a recipe similar to that long employed in Central Asian glass production (Tite et al. 2006: 1284–1285). This change probably occurred due to political instability in the region of the Egyptian Delta, the most important source of natron (Shortland et al. 2006), combined with a massive increase in the demand for natron in general (Tite et al. 2006).

Experimentation in glass production during the early Islamic period is evidenced through scientific analyses of glass found at production sites, such as that located outside the city of Raqqa on the Euphrates (Henderson et al. 2004). Within that complex, a glassworking area, dating to the late eighth to ninth centuries CE and referred to as Tell Zujaj (Fig. 5), has yielded four different types of glass made with ash from different plant types combined with either quartz or sand from varying locations, as well as the addition of recycled natron glass (Henderson et al. 2004). During the early Islamic period, the difficulty of combining these new ingredients is evidenced at Bet She‘arim in the Levant, where failed attempts to produce glass are evidenced by a flawed slab (Walmsley 2007: 118). By the tenth or eleventh century CE, glassmakers had begun to overcome

Islamic Industry, Archaeology of, Fig. 5 A north-south section through an eighth- to ninth-century beehive-shaped glass furnace found at Tell Zujaj, one of the three production sites excavated. (Published with kind permission of Julian Henderson)

the difficulties of making plant-ash glass, as witnessed at Tyre, where an industrial complex comprising four tank furnaces has been identified (Aldsworth et al. 2002).

Many centers in the central Islamic lands were capable of producing their own glass vessels (Walmsley 2007: 118; Carboni and Whitehouse 2001: 14–24). Nevertheless, the pattern of procurement of the raw materials to make those vessels was complex. From specialized production centers such as Tyre, glass chunks were exported to locations including Cairo (Aldsworth et al. 2002: 65). Yet Fustāt (Old Cairo) also manufactured glass from raw materials during the early years of its foundation (Carboni and Whitehouse 2001: 17). The picture is further complicated by evidence for recycling glass cullet from the Serçe Limanı wreck (Brill et al. 2009). In addition, although the fragility of finished glass objects must have made trade in raw glass easier, small objects such as bangles and beads were traded (Robertshaw et al. 2010: 375–376) and larger, highly decorated and presumably prestigious, items were also exchanged. Enamelled glass (see Fig. 3) provides an example of such a prestigious product, made at centers in Mamluk Egypt (notably Cairo) and Syria and distributed widely.

To summarize, owing to the relatively limited range of ingredients used in glass production, the process of manufacture was not as complex as metal, but it did undergo an important period of experimentation in the early Islamic period. As already noted in relation to metal and as discussed in the context of ceramics, the distribution of glass was similarly complex and highly organized, an issue that will be considered further below.

Ceramics

Ceramics are the most commonly encountered artifact produced in the Islamic world with an immense variety of forms and decoration. Clay, the common ingredient in the body, was largely locally sourced but could also be transported in a raw state (Milwright 1999: 507). Although clay always remained a key ingredient in ceramic bodies, by the eleventh century CE, potters adopted a new recipe for ceramic production, possibly to negate the less predictable qualities of material sourced from different locations (Tite et al. 2011). Referred to as "stonepaste," it contained only relatively small quantities of clay combined with quartz and glass (as described by Abu al-Qasim, see above). In contrast to predominantly locally sourced clays, recent analyses of glaze types have indicated that their lead content sometimes originated in regions distant to their production (Wolf et al. 2003).

The vast majority of ceramics in the Islamic world were thrown on a wheel. In the context of Iberia, during the late ninth and tenth centuries CE, the readoption of throwing on a fast wheel in association with the use of ceramic glazes is equated with the "Islamization" of the population (Gutiérrez Lloret 1992). Nevertheless, other types of production did occur, most notably during the twelfth and thirteenth centuries CE in Bilād al-Shām, where handmade geometrically painted ware (HMGPW) dominates ceramic assemblages from rural settlements. Contrastingly, wheel-thrown pottery was made and used at towns and cities, possibly indicating a social and economic divide between urban and rural populations during that period (Johns 1998). Such evidence of technical differentiation must be viewed in light of the economic and social context but can also be informed by ethnographic studies of the production of handmade pottery types (Milwright 2010: 154–156). The vast majority of Islamic pottery, with the exception of types such as HMGPW, was produced in updraft kilns, with a fire pit and chamber for pottery separated by a grill. Such kilns have been identified across the medieval Islamic world, with some of the most recently identified examples, dating to the late seventh to ninth centuries CE, present at the Merv Oasis (Herrmann et al. 1999: 13–15).

The great variety of ceramic types produced can be roughly divided into two categories: highly decorated vessels and coarser, utilitarian objects with little or no decoration other than perhaps a monochrome glaze. Highly decorated forms, both of ceramics and other artifact types, are often regarded as specialized products, made at a few centers and traded widely. As a result of its longevity of manufacture, lustre ware, characterized

by distinctive shiny and metal-like surface decoration, provides an ideal case study through which such patterns of production can be illustrated. Owing to the complexities of its manufacture, lustre ware was a specialized product, probably only made by a relatively small number of craftsmen through whom the technique may have been transmitted to a number of different centers over time (Watson 2004: 38–40). Recent analyses have unlocked the chemical process of lustre production, revealing that it is a nanocomposite metal glass layer, formed during a second firing as a result of a process of ionic exchange between copper or silver oxide paint and the surface glaze (Pradell et al. 2008). This complex production process was first employed in Basra, Iraq, where it was associated with the "Abbasid court," then transferring to Fatimid Cairo, where it was produced for the first time on stonepaste bodies (Tite et al. 2011). During the twelfth century CE, production of lustre ware moved once more, this time to Syria at sites including Tell Minis and Raqqa (Milwright 2010: 150). Further east, Kashan became the dominant production center making lustre and other highly decorated ceramics until the fourteenth century CE, with a cessation in the decades immediately following the Mongol conquest (Watson 2004: 56–57). Scientific analyses (largely ceramic petrology) support this transfer of technology (most recently see Tite et al. 2011).

A survey of ceramic material gathered from Iranian sites, dating to between the ninth and eleventh centuries CE, supports evidence of specialized and centralized production of lustre, while pointing to the more pervasive manufacture of slip-painted wares at multiple urban centers (Williamson 1987). Nevertheless, chemical analyses of lustre wares dating to the mid-twelfth to late thirteenth centuries CE from the Syrian site of Gritille do not support this hypothesis of centralized production, instead indicating that this pottery type may well have been manufactured at multiple, provincial centers in medieval Syria (Redford and Blackman 1997). This evidence concerning highly decorated pottery is, therefore, beginning to provide some clues that multiple production sites making similar wares might, at least in some cases, have been the reality. In contrast to highly decorated pottery, coarse, undecorated wares are often considered to have limited distribution except in the case of storage jars used to contain traded products. For example, amphora dating to the late eighth and early ninth centuries CE, and associated with the wine-making industries of Middle Egypt, was widely distributed in the eastern Mediterranean (Vogt et al. 2002). Furthermore, recent analysis of archaeological assemblages is beginning to indicate the diffusion of other undecorated wares; for example, cooking pots dating to the Almohad period made just outside Seville were distributed at a regional level, in this case to settlements as distant as Mértola on the River Guadiana and Écija on the River Genil (Bridgman 2007; see Fig. 6).

The picture that emerges of ceramic production is, therefore, as varied as the different types of this artifact category, with manufacture probably not following any one set pattern or model. It is no longer possible, therefore, to merely assume that decorated pottery was always a highly specialized and widely distributed product or that plain utilitarian vessels were only made for local consumption. Instead, a picture of pottery production that varied within regions, or even ceramic types, should be posited.

International Perspectives

Centers of Production and Consumption

At many urban centers, industrial complexes produced glass, metal, and pottery objects. Already discussed at Raqqa, glass was made in quantity (Henderson et al. 2004) but this was also accompanied by ceramic production (Milwright 2010: 148). At Merv, evidence for steel smelting and ceramic production has been identified (Herrmann et al. 1999: 13–15; Herrmann et al. 1997: 10–13), while al-Basra's industrial complex manufactured a range of goods including pottery (Benco 1987), glass (Robertshaw et al. 2010), and

Islamic Industry, Archaeology of, Fig. 6 Seville Fabric VI, photomicrograph, identified at sites distant from the city, including Écija and Mértola

metal artifacts (Benco et al. 2002). Links with other industries are also evident at al-Basra, with bone waste from animal butchery (which probably took place nearby) used by metalworkers both as fuel for kilns and as tools for smoothing and burnishing finished metal products (Benco et al. 2002). At Baŷŷāna, the industrial complex incorporated ceramic and glass production, alongside textile manufacture (Acién Almansa et al. 1990). Even where industrial sites have not been identified, it seems most probable that most major urban settlements were capable of producing for their own basic needs, at least in relation to the three artifact categories discussed here. At Nishapur, ceramic kilns have been identified (Wilkinson 1974: xxxvii–xl) and although there is no direct evidence of metal (Allan 1982: 22–23) or glassworking (Kröger and Brill 1995), a large quantity of such objects were recovered from the site, indicating production of all these artifact categories.

If the urban centers discussed here were capable of producing the artifacts required by their populace, then what of the specialized production and trade of goods associated with the medieval and post-medieval Islamic World? Scientific analyses are central to developing understanding of what was doubtless a complex, and most likely differentiated, economic landscape. Analyses of ceramics are at the forefront of such studies, largely due to the range of scientific techniques (for a summary of techniques in relation to Islamic pottery, see Milwright 2010: 152–153), which have long facilitated understanding of their production and consumption. Unlike ceramics, analyses of glass and metalwork are complicated by the multiple stages of production; the possibility of exporting processed materials, such as glass chunks or metal ingots; and the potential for re-melting and mixing of ingredients. Nevertheless, groundbreaking work is increasingly allowing the diffusion of metal and glass objects to be reassessed or identified for the first time. For example, metal lampstands made in a style classified as Egyptian, recovered from Denia and Tiberias, have recently been subject to trace element and isotopic analysis leading to their re-attribution to Syrio-Palestine workshops such as Damascus (Ponting 2008: 58–9). Additionally, the cargo of glass cullet from the shipwreck site of Serçe Limanı, which provides clear evidence of the long-distance trade of this material, has recently been subject to chemical analyses leading to its attribution to a production center at Tyre or possibly Caeseria (Brill et al. 2009). Most recently, strontium isotope analysis of glass objects has

proven a particularly useful tool in assessing the origin of the plants used as an alkali flux (Henderson et al. 2009). Such work, when combined with chemical analyses, is now proven to facilitate identification of regional production signatures for both natron and plant-ash glasses (Leslie et al. 2006). Developments in the field of scientific analyses thus have the potential to broaden significantly our knowledge of the diffusion of manufactured goods on an international scale.

Future Directions

Archaeological research, incorporating excavation of industrial sites and analyses of manufactured goods, thus provides important and unparalleled clues to the levels of organization and specialization in Islamic industries. Artifacts themselves found in consumption contexts provide probably the most plentiful source of evidence on the complexity of industry, demonstrating the range of products produced, evolution and changes to industry, as well as on the diffusion and trade of objects. That evidence combined with studies of industrial complexes is central to the future directions of research on Islamic industry, which should further address the patterns of industry, identifying the extent to which many urban centers produced the goods they consumed, as well as their reliance on a limited number of large, specialized manufactories. Importantly, further investigation of this question will not only develop our understanding of artifacts found in archaeological contexts, and provide possible answers to wider questions of economy and society, but also help us better understand the many examples of Islamic art displayed in museum contexts for which the original provenance is often lost.

Island Archaeology

Helen Dawson
Topoi Excellence Cluster, Freie Universität Berlin, Berlin, Germany

Introduction

The basic premise of island archaeology is to understand how humans used islands in the past. Island archaeology considers the geographical characteristics of insular spaces as a starting point for further analysis, often within a comparative and diachronic framework. In this context,

islands are considered to deserve specialist study, with three approaches featuring more prominently in the literature: (1) islands come in so many different shapes and forms that their comparison can shed light on several types of human/environmental adaptations; (2) they are like "laboratories," i.e., microcosms or simpler versions of the mainland; and (3) they have specific characteristics that set them aside from other geographical settings.

Not everybody agrees that islands are "special" or inherently "different" from mainland situations: coastal and island locations – for instance – share many features, proximity to the sea being the most obvious one. Nevertheless, islands, especially small ones, tend to amplify the effects of geographical and cultural variables, by virtue of being enclosed spaces, completely surrounded by water. Large islands may have more in common with the mainland than with smaller islands, but there are still important insights to be gained from their comparative study. Thus, while islands are not necessarily inherently different from the mainland, the effects of cultural and environmental processes are sometimes more evident on islands than on the mainland and can be more readily studied.

Definition

Island archaeology is the systematic and comparative study of island communities, their cultures, and environments. Islands can be studied both in their own right and as a key to understanding broader issues that may also be relevant to mainland settings. The effects of insularity can be assessed both in geographical and cultural terms, considering changing relations between nearby islands and the mainland, phases of relative isolation and connectivity, and different insular adaptations and cultural identities. Island archaeologists focus on issues including (but not limited to) seafaring, migration, colonization, settlement, abandonment, human-environmental adaptation, animal extinctions and introductions, resource exploitation, and cultural interaction. With respect to insular cultural identities, similarities and differences with nearby islands and mainland communities are equally revealing in terms of understanding shifting degrees of insularity and the extent of cultural interaction.

Historical and Theoretical Background

The development of island archaeology over the last 50 or so years reflects mainstream trends in archaeology, at times experimenting with new methods and theories. As a result, island archaeology has become an eclectic field at a global scale, while retaining a set of defining features. Although island environmental studies still feature prominently on the agenda, a noticeable trend in recent years is the shift towards a greater cultural focus. Key questions remain: in what way does insularity affect culture? And, conversely, do communities actively define their cultures and identity through insularity? Does it matter that it is on an island?

The following two papers provide useful historical and critical overviews of the development of the subject: (1) Matthew Spriggs (2008) wrote a chapter for a book entitled "Islands of Inquiry. Colonisation, seafaring and the archaeology of maritime landscapes" (edited by Geoffrey Clark, Foss Leach, and Sue O'Connor); (2) Cherry and Leppard (2014) wrote a review of island archaeology with a focus on the Mediterranean in "The Cambridge prehistory of the Bronze Age – Iron Age Mediterranean" (edited by Bernard A. Knapp and Peter Van Dommelen). Elements of this entry are also drawn from published and forthcoming work by the current author (Dawson 2014).

Following the "diffusionist" or "migrationist" paradigm prevalent in the 1950s–1960s, islands were originally considered as places vulnerable to outside influences or, alternatively, as backwaters, effectively isolated from mainstream change. As Spriggs (2008) points out, it was Margaret Mead (1957) who introduced the concept of "islands as laboratories" (whose origins can be traced back to early European travelers to the Pacific) to

mainstream academia in the 1950s. According to this principle, islands are ideal laboratories for studying ecosystems and societies, not because of their intrinsic isolation, but rather because "by studying clusters of islands, biologists view a simpler microcosm of the seemingly infinite complexity of continental and oceanic biogeography" (MacArthur and Wilson 1967: 3). A paper by Vayda and Rappaport on "Island Cultures" (1963) explained how this might work in practice, by spelling out some key principles: the so-called "founder" effect could explain why island communities diverge from their mainland parent populations (because of the limited size of the founder population), while the "rescue" effect explained why extinction is less likely to occur on islands that are within "commuting" distance of a replenishing source. These ideas were expressed mathematically in a seminal book entitled *The Theory of Island Biogeography*, by MacArthur and Wilson (1967). The authors formulated a theory, which stated that immigration and extinction on an island would reach equilibrium over time and that this process was affected by island size and distance to the mainland (or intervening stepping stone islands). Simberloff and Wilson (1969) subsequently devised an experiment to prove the theory and were able to demonstrate the effects of distance, in terms of relative and differential isolation, on island arthropod populations. Such "controlled conditions" (measureable in terms of size and distance) made islands similar to a natural laboratory.

In the 1970s, "processual" archaeologists began to adopt these ideas and engage with islands in their own right, emphasizing local developments and – inspired by the scientific rigor of island biogeography – searching for general and cross-cultural questions. Evans (1973) introduced the laboratory analogy to the Mediterranean islands. By this time, the radiocarbon revolution had revealed the fallacy of the diffusionist paradigm: for instance, in the Mediterranean, the megalithic cultures of Malta were shown to be much earlier than the Mycenaean remains that ought to have inspired them. Evans noted that the islands in the Mediterranean were not as remote as those in the Pacific, yet he considered the development of Malta's unique temples as the result of the island's cultural isolation during that particular period in prehistory. While he conceded that the Mediterranean was a highway rather than a barrier for contact, the idea of islands developing distinct cultures in isolation had a lasting legacy among Mediterranean archaeologists.

In 1981, Cherry wrote an article applying island biogeography in the Mediterranean using the area/distance parameters to explain differences in the rates of island colonization, an approach that for initial (Neolithic) settlement still holds relevance even in light of new data and discoveries some 20 years later (Dawson 2014). Island biogeography takes into consideration also cultural factors which may explain how communities overcome spatial limitations: distance (in terms of travel time) can effectively shrink through progress in boat technology (e.g., paddling vs. sailing), and even size and elevation have a relative rather than absolute effect on island settlement (such limitations can be overcome, e.g., through terracing or networks).

Cyprian Broodbank (2000) drew inspiration from the Pacific for his study of the Cycladic islands (Greece), where he adapted Terrell's (1977) "proximal point analysis" to predict patterns of connections between different islands and used it to develop his "islandscape" approach. This marked an important shift in island archaeology in the Mediterranean, which until then had been preoccupied with islands being isolated rather than being connected. Broodbank instead viewed insularity as "culturally constructed," "historically contingent," and "liable to change" (2000: 13).

Further developments were contained in a volume edited by Scott Fitzpatrick in 2004. Biological endemism can be explained by physical isolation (or the unlikelihood of plants and some animals to cross water bodies unaided); in contrast, water does not pose a barrier in the same way for humans. Since cultural isolation rarely occurred, the application of the "islands as laboratory" in archaeology is problematic and can

work only as long as we recognize that it is the archaeologists themselves who treat islands "*as if* they were isolated" (Terrell 1999: 241, in Fitzpatrick 2004: 5). The "idea" of a boundary sets islands aside from the mainland (Fitzpatrick 2004: 7) and emerges from the fact that they are well defined spaces: according to Terrell (1999: 240), they represent "living spaces surrounded by a considerable shift in habitat." Our ability to perceive of these spaces as distinct places is not limited to islands (it can also apply to other spaces surrounded by changes in habitat, such as enclosed valleys or oases); however, islands are more easily comparable, which makes them particularly attractive case studies.

In 2007, Paul Rainbird expressed his concerns regarding the legitimacy of an island archaeology approach arguing instead in favor of an archaeology of the sea, emphasizing similarities between island and coastal communities, as opposed to differences, thus ultimately focusing on connections rather than on isolation. His focus on the sea, however, treats island communities as consistently maritime in character, which is not always the case. In a volume entitled "Comparative island archaeologies," Conolly and Campbell (2008: iii) also argued that islands are not "privileged spaces to understand the past" while claiming that "islands are still good places to 'do' archaeology." Later on, they admit that islands "offer a *unique perspective* on human ecology because of their (usually) geographically circumscribed nature" (2008: 111, my emphasis). These statements, in apparent contradiction with each other, underline the evident paradox at the heart of island archaeology, which can be summed up as follows: "the separation of islands facilitated interaction" (Fitzpatrick 2004: 9). Assessing a community's relative isolation and connectivity and their effects over time, both in light of geographical categories and historically contingent factors, remains the real strength of a comparative island archaeological approach. Though tempting, it is hard to generalize about islands: island archaeology "implies comparison of insularity at different places and periods" (Renfrew 2004: 282).

Island archaeology has developed more readily in the Pacific and in the Mediterranean, with a few notable exceptions. Curet (2004: 187) lamented "the near absence of the Caribbean in the debate surrounding issues of island archaeology" while arguing that the archaeological record from the Caribbean islands "contradicted . . . the idea of islands as appropriate units of analysis," since communities on adjacent islands often had more in common than with people on opposite sides of the same island (Curet 2004: 191). In contrast, the editors of the recent *Oxford Handbook of the Caribbean Archaeology* stated in their introduction that the island provides a useful point of departure given that "at a general level of comparison, cultural differences in the Caribbean correspond to differences in the islands and their configurations" (Keegan et al. 2013: 3).

The comparison between geographical and cultural units is therefore one of the strengths of an island archaeological approach. Identities and cultures are not bounded in the same way as space: culture spills over the edges of geography. Anthropologists have noted that cultural groups are very rarely isolated, on the contrary they tend to develop from interaction (Eriksen 1993). Islands are not closed microcosms, but they provide fertile grounds for the comparative study of cultural interaction, which may result both in cultural similarities and differences, and contribute to the creation of distinctive island identities.

Island archaeology also has potentially a great contribution to make to island communities in the present. Such communities are braced against considerable challenges and – in extreme cases – threats to their natural and cultural heritage, mostly arising from the effects of climatic and environmental change. Numerous initiatives (such as the IHOPE Islands project) are developing policies to tackle these issues. Islands are often considered to illustrate how humans have impacted on the environment, whether positively and negatively, and to provide particularly good examples of both vulnerability and resilience. Islanders may act shortsightedly, wreaking an ecological catastrophe on themselves;

alternatively, they may be custodians of precious traditional knowledge that can be used to mitigate such threats. Easter Islanders are a case in point: they have been portrayed both as responsible for their own "eco-suicide" (Bahn and Flenley 1992) and as a "sustainable society" (Hunt and Lipo 2011). The unfortunate down-side of such polarized views is that they tend to turn islands into stereotypes: vulnerability and resilience are not absolute categories, rather their meaning has to be contextualized (Kelman 2018). Such discussions should take into account what islanders themselves have to say (Kelman 2018).

Island Archaeology in Practice

Archaeological survey has a long tradition in island archaeology and – especially when combined with excavation and palaeoenvironmental reconstructions – is arguably the most productive tool for island investigation as it allows comparative and diachronic study (see "Further Reading" for examples). Island survey is closely allied to spatial analysis, with Geographical Information Systems in particular being widely applied to survey data in order to study changing site distributions in time and space. GIS-based spatial analysis focuses not just on intra-island site relations but also at the inter-island scale, for example, using intervisibility analysis and modeling maritime travel. Underwater surveys encompass the seascape (submerged coastlines, structures, shipwrecks) and combined with terrestrial surveys can tell us about maritime contact (e.g., exotic materials, which might indicate long-distance exchange).

Network analysis is another natural ally of island archaeology since it captures connections at multiple scales (see "Further Reading" section). Islands or sites within them provide easily recognizable nodes, and evidence of contact can be used to connect them and create "edges" (or links) in order to reconstruct a network. Network analysis can be used – for example – to explain why islands lacking resources may support a sizeable population, to explain the success of a community as it benefits from the network and its potential decline if it relies excessively on the outside world for survival. Networks can be descriptive (presence/absence or frequencies of certain classes of material) and exploratory. Point Proximal Analysis (PPA) was one of the first applications of network analysis employed by archaeologists (and all it required was a pencil and ruler! John Terrell pers. comm. 2018). In PPA, each node is linked to its nearest three or four neighbors; these can either be sites that are geographically nearest or share the highest similarity with respect to certain archaeological features. Nodes may represent known sites or hypothetical locations and those with more connections are considered more central. PPA can also adopt a "fixed radius" model to simulate the creation of networks: here all the nodes that lie within a certain distance are connected. Terrell (1977) pioneered this in his study of the Solomon Islands and Broodbank (2000) to his study of interaction in the Bronze Age Cyclades, which simulated the range of travel of a canoe and sailing boat.

Islands offer useful case studies also for exploring qualitative aspects of space. A distinct feature of islands is their "sense of place," which arises from their being bounded by the sea, and is particularly evident on smaller islands, where the coastline is more conspicuous. Studies of present-day islanders suggest that such clear terrestrial boundaries foster a strong sense of community derived by geography: physical containment results in strong place identification. Archaeologists working on islands have begun to explore these insights through phenomenological fieldwork, employing methods that highlight specific qualities of insular spaces (e.g., stone quarrying on Easter Island, see section on "Further Reading").

Key Issues/Current Debates

Island archaeology is an interdisciplinary endeavor that combines environmental and

cultural approaches. It is about understanding degrees of isolation and connectivity: an island may be geographically remote/close, and culturally inward/outward looking, but there are no general rules and ultimately insularity is shaped both by geography and culture. Although cultural isolation is not a necessary consequence of physical containment, islands are broadly considered as more isolated in comparison to noninsular location. The sea is not a barrier for contact, but the effects of winds and currents on seafaring technology at different times cannot be ignored either: connectivity takes place *despite* the obvious challenges of insularity.

In the Pacific, for example, there is still little agreement on the relative weight of archaeological, biological, and linguistic data in substantiating both isolation and interaction (Cochrane and Hunt 2017). Theories on the colonization of this region differ between a phylogenetic approach (a common ancestral population split into separate groups that colonized separate islands or archipelagos and underwent cultural, linguistic, and biological evolution in relative isolation) and a reticulate approach (cultural similarities and differences cannot be explained by branching patterns of descent but by patterns of relatedness) (see discussion in Cochrane and Hunt 2017).

Another current debate surrounds the increasingly earlier evidence of island colonization emerging from the Pacific (recently reviewed by Bellwood in 2017) where hominin occupation currently goes back to at least a million years ago and modern human occupation to at least 50,000 years ago (see "Further Reading" for individual references). Homo floresiensis, popularly known as "the hobbit," made headlines when it was first discovered in 2003 on the island of Flores, as it was shown to be a new species, somehow capable of crossing water and colonizing new land. "Hobbit" fossils belonging to a number of individuals at the Liang Bua cave were arguably dated to between 95,000 and 17,000 years ago. Different locations in Flores have since yielded tools often associated with butchered animal remains: they were dated to about one million years BP (at a site called Wolo Sege) and 700,000 BP (at Mata Menge, where hominin remains were also found). If they represent hobbit's ancestors, the species' prolonged isolation could explain the dwarfism. Recent reports from the Philippines (at Kalinga cave) also place their earliest colonization date around 700,000 BP.

Evidence pertaining to our own species is usefully summarized in the recent *Oxford Handbook of Prehistoric Oceania* (O'Connor and Hiscock 2017): an open sea crossing was necessary to reach Sahul (a palaeolandmass comprising Australia, Tasmania, and New Guinea) from Sunda (an area now submerged along the edge of southernmost Eurasia). This happened over 50,000 years ago and required navigating across the vast region of Wallacea with its 17,000 islands. Remains at the Callao Cave (northern Luzon, Philippines) were directly dated to circa 67,000 BP: they may represent the descendants of the Kalinga cave occupants or a new wave of colonization. In Near Oceania, the earliest occupation in the Bismarck Archipelago to the northeast of New Guinea, and caves sites in East Timor, has been dated to ca. 43,000 years BP and in surrounding islands ca. 20,000 years ago.

This growing body of evidence has important repercussions for our understanding of subsequent migrations out of Africa and associated seafaring capacities – whether the sea posed a barrier or a passage for mobility, both for our species and earlier ones – and the purposefulness or accidentalness of such endeavors. The evidence of such early water crossings from Island South East Asia has given an impetus to research elsewhere, with archaeological fieldwork targeting areas that could represent likely landfalls and favorable ecological niches. The earliest evidence for island colonization in the Mediterranean at present comes from the Aegean (see "Further Reading" section). Recently discovered stone tools in Crete and Naxos have been dated to the Lower and Middle Palaeolithic (as early as c. 300,000 BP). This early dating has been challenged on a number of accounts: there are no actual anthropological remains and the sites are dated indirectly (either on typological grounds or based on the geological strata where the tools were embedded). Work on both islands is ongoing.

International Perspectives

While still relatively "young," island archaeology has already developed a strong international outlook. While the southern Pacific remains its natural "home," advances in the Mediterranean especially, followed by the northern Pacific and Caribbean, have been particularly significant in the last two decades. In contrast, archaeologists working on Africa's islands and in the Indian Ocean are yet to fully engage with these debates (see "Further Reading").

Island archaeology is also becoming more integrated into the broad field of island studies, which is likely to prove highly beneficial since new insights can be gained from the study of present-day island communities and the issues they face. Current debates can be relevant to our understanding of past communities; in return, the archaeological record anchors such issues to a long-term perspective (the journal Shima is a prime example of this potential).

Future Directions

Island archaeology is of growing interest and concern as islands are at the forefront of global environmental change. Islands are still relatively unexplored so that there is great potential for new discoveries and for their continued contribution to cognate fields of study, particularly landscape, environmental, and bioarchaeology (in particular, stable isotope and aDNA analysis with regards to processes of island colonisation). Islands' contribution to archaeological theory has already been outlined above and will continue to be a fertile testing ground in the future, as it encourages both categorical and relational thinking. Finally, island archaeology may be going through a revival of the "island laboratory" concept, as researchers reconsider the value of considering global issues through the lenses of insularity. As the systematic study of islands continues to shed light on human-environmental adaptation, it is becoming increasingly relevant to society. The study of islands communities, past and present, holds great potential for the future, in terms of understanding current societal concerns, environmental challenges, demographic movements, and the issues faced by small communities in a context of globalization.

Island Nation Sites and Rising Sea Levels

Donald Kerr
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Island nations around the world face major challenges to protect their heritage in the twenty-first century as sea levels rise, flooding low-lying coastlines and damaging or destroying significant cultural sites. Many countries surrounded by seas are affected by inundation with some low-lying Pacific islands with coasts only a few meters above sea level already damaged or partially abandoned. Traditional ways of life have changed as people try to protect their homes, lands, gardens, and cultural sites, or abandon them to move to higher ground. Rising sea levels have severely disrupted some island cultures but rejuvenated others as people forge stronger kinship links to cope with climate change.

Rising sea levels and storms, cyclones, tsunamis, and tidal surges have filled island bays, lagoons, rivers and eroded banks, beaches, deltas, headlands, and peninsulas along coast lines where many people live closer to the water, rarely more than 3–4 m above average sea levels (Henry and Jeffrey 2008: 13). Significant cultural sites have been washed away, waterlogged, damaged by salt, or submerged. These include landscapes, buildings, monuments, temples, graveyards, and middens. Iconic World Heritage cultural sites such the City of London and Timbuktu and natural places such as surf beaches, fishing and hunting grounds, tropical rainforests, and coral reefs are also threatened.

Definition

Vulnerable island nations include both large continental islands and archipelagos and small island and atoll states in Europe, Africa, Asia, the Middle East, and Oceania. Countries identified at the greatest risk of inundation have been identified using data from scientific studies based on United Nations predictions of sea level increases in the twenty-first century by the UN's fourth Intergovernmental Panel on Climate Change (Core Writing Team et al. 2007: 44–6) and confirmed after 5 years by the United Nations Framework Convention on Climate Change (UNFCCC 2005) at the Doha Climate Change Conference. The countries at risk include Australia; New Guinea; New Zealand; Britain; Bali, Indonesia; Cebu, Philippines; Chuuk; Eastern Island, Chile; Hainan, People's Republic of China; Hawaii, United States; Jejudo, South Korea; Loyalty Islands; the Maldives Islands; the Marshall Islands; Tuvalu; Tokelau; Kiribati; Phuket, Thailand; Prince Edward Island, Canada; Riau Islands Province and Western Province; and the Solomon Islands.

> Coasts have been modified and intensively developed in recent decades and thus made even more vulnerable to higher sea levels. Developing countries with their weaker economies and institutions face the gravest risks, but the low-lying coastal zones of developed countries could also be seriously affected. Given the present degree of protection, a sea-level rise of one metre would cause estimated land losses of 0.05% in Uruguay, 1% in Egypt, 6% in the Netherlands, 17.5% in Bangladesh, and up to about 80% for Atoll Majuro in the Marshall Islands (UNFCCC 2012).

Even a large continental island such as Australia faces a threat to its indigenous and historic sites caused by erosion from rising seas. Australian researchers have found that Aboriginal sites on the foreshores of Middle Harbour, in Sydney's heart, are among places that face devastation, with possibly a quarter of all sites likely to be damaged or destroyed by rising sea levels and wave wash (McIntyre-Tamwoy 2008: 7). As Henry and Jeffrey (2008: 13) point out:

> Surrounded as they are by vast expanses of ocean, it is clear that small island states are at the forefront of the vulnerability in relation to the potential adverse effects of climate change, including sea level rise in sea surface temperature and increased intensity and frequency of extreme weather events.

Key Issues/Current Debates/Future Directions/Examples

Natural Climate Change and Sea Level Rise in Prehistoric Times

Sea levels have risen and fallen periodically due to natural causes throughout the Earth's history, flooding and exposing coastlines and damaging heritage sites. The International Geosphere-Biosphere Programme (IGBP) has reported that new records from Israel, Tasmania, Alaska, and Greenland for the last centuries to millennia showed that sea levels responded to moderate climate changes during the Medieval Climate Anomaly (c. 950–1300 CE) and the Little Ice Age (c. 1450–1850 CE). The IGBP stated that:

> During the last interglacial (c. 125,000–114,000 years ago) – at a time when climate was a few degrees warmer and overall sea level several metres higher than today – new coral data from the Bahamas indicate that rates of sea-level rise were significantly faster than during the late Holocene (the past three millennia). This suggests that the ice sheets were less stable in conditions slightly warmer than today (IGBP 2011: 20).

The land bridges between Australia and New Guinea were submerged during the Holocene, cutting off close contact between Australian Aborigines and neighboring New Guinea tribal groups to the north and south, a separation that led to social changes as interaction across borders was reduced and cultural diffusion slowed (Mulvaney and Kamminga 1999: 261). The disruption to the flow of ideas, beliefs, genes, tools, and technologies led the separated Australian and New Guinean societies to develop strategies to preserve cultural contact. Long-distance trade journeys by canoe between Australia and New Guinea across the Torres Strait helped to maintain kinship ties, encourage trade, and reinvigorate cultural values. "Some parts of the [Australian] continental shelf were so low-lying and had such a low gradient that during periods of accelerated sea level rise the shoreline migrated inland at the phenomenal rate of one metre per day" (Mulvaney and Kamminga 1999: 273).

Contemporary Human Activity and Climate Change

In the past millennia, human activity including the development of intensive agriculture, establishment of cities, and the industrial revolution has been shown to contribute to climate change. Island nations have had to draw on their experiences of natural climate change during prehistory to deal with the outcomes of anthropogenic activity that have warmed the planet. Polar ice caps and land-based ice sheets have melted further and ocean water has expanded, raising sea levels still further. "The climate of our planet is changing. The climate has always been variable, but today there is a growing concern over climate change issues, perhaps because the magnitude of the change seems to be unprecedented but, more importantly, because there is strong evidence to suggest that humanity might be directly responsible for climate change," the United Nations Educational, Scientific and Cultural Organization (UNESCO 2007: 12) has found.

Forest clearing, burning fossil fuels, farming, and industrial development during the past millennia have allowed the release of more greenhouse gases including carbon dioxide and methane into the atmosphere, trapping heat on the planet's surface, melting ice caps, and warming oceans. The International Geosphere-Biosphere Programme has warned: "In addition to the large carbon sink, scientists now know that deforestation is responsible for emitting 2.9 billion tonnes of carbon per year – an exchange that had not been quantified in the past because of a lack of data. For comparison, total emissions from fossil fuels are currently above eight billion tonnes of carbon per year" (IGBP 2011: 21).

United Nations Concerned Deltas and Small Islands Vulnerable

The United Nations' Intergovernmental Panel on Climate Change (IPCC) has suggested that deltas and small island states are particularly vulnerable to sea level rise caused by both thermal expansion and ocean volume. The 2007 Fourth Assessment Report (AR4) by the IPCC indicated that during

the twenty-first century, sea levels are expected to rise another 18–59 cm (7.1–21 in) (Core writing team et al. 2007: 44–6). "Anthropogenic warming and sea level rise would continue for centuries due to the time scale associated with climate processes and feedbacks even if GHG [Greenhouse Gas Concentrations] were to be stabilized" (Core writing team et al. 2007: 44–6).

Sea level changes caused by human activities have been proven to result in environmental, humanitarian, or economic losses to small island states. The IPCC has forecast that thermal expansion will cause most of the increase in sea levels during the twenty-first century; however, other factors not directly related to climate change can also raise or lower sea levels. Subsidence, tectonic forces, submergence, and postglacial rebound too affect sea levels (Rowland 2008: 24).

ICOMOS Develops Strategy to Protect Cultural Heritage

The International Council on Monuments and Sites (ICOMOS) has developed a strategy to protect global heritage sites from the effects of climate change by giving priority to sites that can be saved and those which are considered unlikely to be salvageable, which can be documented or have archaeological salvage and research carried out. The ICOMOS Scientific Council Symposium on Cultural Heritage and Global Climate Change (2008: 1–3) described the issues as "managing static remains in a dynamic landscape" . . . climate change accelerates and magnifies the dynamism of the landscape."

The Scientific Council identified 13 areas where cultural heritage would be affected: polar heritage, earthen architectural heritage, stone, fortifications, structural stability, twentieth-century heritage, archaeological sites, vernacular, historic villages and cities, training, cultural tourism, intangible heritage, cultural landscapes, and heritage ensembles and interpretation. "All of these examples underline an important dimension of global climate change as it impacts cultural heritage, namely, that it is often about loss and destruction as much as preservation. In the cases where the loss of cultural heritage resources cannot be prevented or mitigated, its significance actually transforms itself from that of tangible to intangible heritage. Monuments or natural features documented before their destruction become cultural memories" (ICOMOS 2008: 4).

United Nations Cites World Heritage List Sites at Risk

The United Nations Educational, Scientific and Cultural Organization (UNESCO) report, Case Studies on Climate Change and World Heritage, has highlighted the dangers posed by rising sea levels and flooding to sites on the World Heritage List in Europe, Africa, and the Middle East and the need for international action to prevent further damage. The Director General of UNESCO, Koïchiro Matsuura, stated that the international community generally agreed that climate change would be one of the twenty-first century's major challenges and a coordinated approach to issues such as environmental preservation and sustainable development was needed (UNESCO 2007: 5).

UNESCO has warned that rising sea levels and flooding could devastate buildings and historic settlements and cities, citing the World Heritage places of the City of London and other European sites, Timbuktu and Mali in Africa, and, in the Middle, East Ouadi Qadisha and Lebanon's Forest of the City of God. These sites are vulnerable to the aftereffects of flooding such as a buildup of salt on buildings which damages decorations including paintings and frescoes, while rises and falls in ground level destabilizes buildings as changes weaken foundations and crack walls. Conservators and restorers face the complex task of dealing with the interactions between the natural, cultural, and social elements of conservation (UNESCO 2007: 52, 53).

Rising Sea Levels Threaten Traditional Island Cultures

Chuuk, in the Federated States of Micronesia, faces major challenges from rising sea levels that threaten to cover its many small outer coral atolls and islands, disrupting traditional ways of life as many

people live on the coast close to the ocean close to their land. Hezel observed that land and life were inextricably tied together for Melanesians who regard ownership as part of being fully human. "If land was life for traditional Melanesians, then loss of land was a form of death: in Chuuk, according to one author (Parker 1985) it was lamented with the cry "I am no longer alive" (Hezel 2001: 34–5).

In traditional island societies, land ownership and kinship systems are closely tied. Damage caused by climate change to significant natural and human-made places can have profound effects on cultures, leading to changes in social structures and customs, language, knowledge, traditions, and mythology. The loss of traditional lands for islanders has profound consequences for their societies with some people forced to try to protect cultural sites by building sea walls or even to abandon them and move to higher ground. Societies have adapted to the effects of weather and climate change to protect themselves from harm caused by such events as floods, storms, and droughts. However their ability to cope with the increasing impact of rising sea levels may be stretched beyond their ability to cope (Core writing team et al.: 2007 56).

Island governments have now recognized that to counter the effects of rising sea levels on Pacific islands, strategies need to be integrated with social and economic factors such as development and humanitarian issues to create effective regional responses rather than being driven by central administrations (IGBP 2011: 18). Some island states have to deal with a combination of such factors as large populations in coastal areas prone to hazards and a limited capacity to respond effectively to disasters. "Vulnerability and related assessments in the Pacific are now better aligned with the realities of the circumstances of small islands," according to the International Geosphere-Biosphere Programme (IGBP 2011: 18).

Paradoxically, loss of significant heritage sites submerged by rising seas may also spur renewal of island cultures. Traditional ties to land broken by dispossession can be strengthened by forging new social connections to survive change and by drawing upon historical knowledge.

> In terms of indigenous cosmologies too, there exists narrative knowledge of the dynamic nature of island formation in the past and local acceptance of the possibility of such environmental change – stories of islands disappearing into the sea, or either being either thrown down 'fished up' by various ancestral beings or culture heroes (Leasa 1961, in Henry and Jeffrey 2008: 13).

In traditional societies, a past strategy that helped to renew cultural ties during times of turbulent change was to strengthen kinships and exchange networks between low-lying coral atolls and neighboring high islands. ". . . Loss is also a productive notion, creative of heritage values celebrating social practices and tenure regimes, indigenous knowledge, economic and political institutions, exchange networks that become key tools for resilience and adaptation" (Henry and Jeffrey 2008: 17). Islands surrounded by seas have found ways to integrate their culture and changing maritime environment by conceiving of them as positive elements in social development. Rainbird (2004: 53) describes social flows as being linked to "heritage values of a cultural landscape constructed in terms of movement, so that rather than being a barrier, the sea is conceptualized as a 'way' or 'pathway' of connection."

Conclusion

In summary, the extent and effects of sea level rise on island states and nations are still being studied and the outcomes may not be known for many years. Damage or destruction of heritage by inundation has a significant effect on traditional cultures, which are closely tied to land ownership and linked through kinship systems. The experience of the loss of lands, homes, and important places from rising seas in the past is deeply embedded in the memories of traditional societies, and the lessons learned have developed their resilience, ability, and determination to survive. The ability of island societies to revitalize their traditional cultures during times of major change by celebrating indigenous social practices can also have a protective effect and help them to overcome the sense of loss and develop a new identity.

Island Southeast Asia: Neolithic

David Bulbeck
Department of Archaeology and Natural History, The Australian National University, Canberra, ACT, Australia

Introduction

Island South East Asia (ISEA) comprises the tropical islands lying in between Mainland Southeast Asia (MSEA) and Taiwan to the northwest and Australia and New Guinea to the southeast (Figure 1). The western islands lie on a shallow continental shelf, the Sunda Shelf, and were connected to MSEA during the Pleistocene. The eastern islands that have been separated from the mainland and from each other by deep marine troughs include the Philippines (east of Palawan), Sulawesi, northern Moluccas, and the Nusa Tenggara ("southeast") islands. Accordingly, colonization of eastern ISEA by anatomically modern humans (AMH), leading to the colonization of Australia and New Guinea by 50,000 years ago, would have required watercraft capable of transporting groups of people numerous enough to establish viable daughter colonies. By 5,000 years ago, on the eve of the Neolithic, all of the large islands and many of the small islands of ISEA were settled by foragers whose most consistent archaeological signature is flaked stone artifacts (Bellwood 2017).

The Holocene climate of ISEA is generally monsoonal, or permanently wet near the equator which is impacted by both the northern and southern hemisphere monsoons. Across most of ISEA, even in rain shadow localities, access to fresh water is adequate, apart from pockets (especially in Nusa Tenggara) that face a chronic danger of drought. The long coastlines of ISEA provide many of the inhabitants access to abundant marine, littoral, and mangrove resources, but terrestrial resources are unevenly distributed. For instance, floral diversity and the opportunity for

Island Southeast Asia: Neolithic, Fig. 1 Island South East Asia: Neolithic sites mentioned in the text

extraction of forest produce generally correlate with rainfall, while native mammalian diversity is highest on the largest islands on the Sunda Shelf and low across Nusa Tenggara.

The period of ethnographic contact began in the sixteenth century when competing European powers intervened in ISEA's maritime trade, notably the Moluccan spices. By this time, the great majority of ISEA's inhabitants spoke languages belonging to the Malayo-Polynesian branch of the Austronesian family, including the Philippine "Negritos" and many of the Moluccan/Nusa Tenggara inhabitants, whose dark skin and coiled hair distinguished them from most other ISEA inhabitants with their "Mongoloid" phenotype. Reliance on pottery and iron tools was firmly established across ISEA, associated with a variety of subsistence regimes that ranged from intensive wet-rice agriculture to swidden horticulture and specialized maritime and/or terrestrial foraging. Large kingdoms had evolved, with an economic base in wet-rice production and/or entrepôt trade, but small-scale societies were widespread, including small chiefdoms (with an agricultural basis) and egalitarian societies (often based on a foraging economy). The ISEA Neolithic, and the Early Metal Age that followed it, were a bridge between the stone-flaking foragers of the mid-Holocene and ISEA's kaleidoscope of ethnographically recorded societies (Bellwood 2017).

Definition

ISEA is defined here as the triangle of islands lying between the Philippines, Aru (southern

Moluccas), and Sumatra, excluding the Malay Peninsula. As explained by Spriggs (2011), the ISEA Neolithic is defined by the appearance of earthenware pottery. Thus defined, it broadly covers the period 4,000–2,000 BP ("before present"), but with an earlier onset in the northern Philippines (Bellwood and Dizon 2013) and a later onset in some remote locations such as the Lake Towuti region in Sulawesi (Bulbeck et al. 2016). Neolithic contexts also often include stone artifacts polished over much or all of their surface and sometimes reveal evidence of farming such as traces of rice in pottery and skeletal remains of domesticated animals (Bellwood 2017). Small bronze artifacts have been documented in a couple of sites prior to 2,000 BP (Lloyd-Smith et al. 2013; Fauzi et al. 2016), but the appearance of large ceremonial bronzes and iron metallurgy were Early Metal Age developments (Bellwood 2017).

Historical Background

Early archaeologists working in ISEA embraced the chronology of successive "ages" established by John Lubbock for Europe, and so recognized the Neolithic ("New Stone Age") on the basis of adzes and other tools of polished stone (Van Heekeren 1972). Some association of the ISEA Neolithic with the spread of people with Mongoloid physical features and an agricultural subsistence was also widely aired; an early statement of this proposition is provided by Van Heekeren (1972: 203). With the development of radiocarbon dating, chronological guesswork on the antiquity of the Neolithic was replaced by radiometric determinations in Malaysian Borneo, the Philippines, and East Timor during the 1950s and 1960s, and finally in Indonesia in the 1970s (Bellwood 1978). In the 1980s, as a greater number of sites were dated, archaeologists focused on the appearance of pottery rather than polished stone tools as the touchstone for recognizing the Neolithic in ISEA (Spriggs 1989).

From the 1960s into the 1980s, archaeologists dated the origins of the ISEA Neolithic to the sixth millennium BP, approximately the same age as the oldest dates known at the time for the Neolithic in Taiwan. Spriggs (1989) trimmed the initiation date in ISEA back to 5,000 BP by rejecting dates on freshwater shell in limestone regions and other dates from clearly insecure contexts, and so agreed with the emerging view that Austronesian speakers with a homeland in Taiwan introduced the Neolithic to ISEA. Subsequent rejection of dates from rockshelter contexts with a small number of pottery sherds, probably displaced downwards from the overlying Neolithic levels, led to an even more conservative estimate of 4,000 BP for the spread of the Neolithic across ISEA. There are a couple of anomalously early dates but these are arguably insecure: the c. 5,000 BP date on charcoal near a flexed burial associated with a polished stone adze and four polished shell adzes, interred into a preceramic shell midden at Duyong Cave in the Philippines; and the c. 4,500 and 4,300 BP dates from the lower pottery layers at Gua Sireh, Sarawak (discussed below). Excluding these dates, a 4,500–4,000 BP date on pottery food residue in the Batanes Islands would be the "exception that proves the rule," because the location of these islands between Taiwan and Luzon would have made them the ideal stepping stones for the movement of the Neolithic from Taiwan to ISEA (Bellwood 2017).

The archaeologist most responsible for developing a large empirical basis to address the ISEA Neolithic is Peter Bellwood. Working with counterparts in Indonesia, Malaysia, and the Philippines, Bellwood led a series of ambitious field projects in northern Sulawesi, Sabah (northeastern Borneo), the Moluccas, and the Batanes Islands between the 1970s and the 2000s. The Batanes project is especially noteworthy in (1) adopting a "landscape" approach that allowed the identification of a range of open-air Neolithic sites in addition to the more easily locatable rockshelters and shell middens, (2) targeting an area that appears to have been free of pre-Neolithic occupation, and (3) documenting the pristine material culture and settlement system of the Malayo-Polynesian speakers who subsequently dispersed across ISEA (Bellwood and Dizon 2013). Bellwood also supervised postgraduate students from Indonesia, Sarawak, the

Philippines, and Taiwan, whose projects have resulted in major contributions to our knowledge of the ISEA Neolithic. Of particular interest are the excavation by Hsia-chun Hung at Nagsabaran (Oxenham et al. 2016), one of a series of shell middens strung along the Cagayan River in northern Luzon, and the excavations by Anggraeni (2012) at Kamassi and Minanga Sipakko, two buried habitation sites on the Karama River in West Sulawesi.

Other prominent researchers whose investigations have touched on aspects of the ISEA Neolithic include Ian Glover (1976, 1986), who excavated East Timor sites in the 1960s and South Sulawesi sites in the 1970s, and Dominik Bonatz (2009), who has led investigations into the megaliths of highland Sumatra and their Neolithic precursor at Bukit Arat. Three particular projects are notable in the following respects: their recent revival of a research initiative that traces back to the mid-twentieth century, and their discovery of major information on the Neolithic within the context of an occupation sequence that extended back tens of thousands of years.

One of these projects involves cave sites at the eastern tip of East Timor, including Lene Hara which was first excavated by the Portuguese archaeologist Almeida in the 1950s. Discoveries germane to the Neolithic (O'Connor 2015) include direct dating (on bone) of a dog burial and translocated fauna (civet cat from the west, possum from the east) to around 3,000 BP, as well as conclusive documentation of terminal Pleistocene to mid-Holocene jewelry and fish hooks of shell, which have conventionally been interpreted as Neolithic introductions to ISEA. Importantly, in this context, it is now clear that polished shell adzes were manufactured in the central Philippines and the Moluccas (and Papua New Guinea) by the early middle Holocene, potentially supporting a mid-Holocene date for the Duyong flexed burial (Pawlik et al. 2015) but certainly earlier than the shell adze interred at the Neolithic cemetery of Pain Haka in Flores (Galipaud et al. 2016). The second project concerns the Niah Caves in Sarawak, which had been intensively excavated by Tom and Barbara Harrisson in the 1950s and 1960s. The multidisciplinary investigations led by Graeme Barker have allowed his team to securely date the site's main Neolithic cemetery and describe the mortuary customs and burial goods of the most bounteous Neolithic cemetery yet documented for ISEA (Lloyd-Smith et al. 2013). The third project is Michael Morwood's extension of R.P. Soejono's excavation of the Liang Bua cave, on Flores, discovered by the Dutch antiquarian Verhoeven in the 1960s. In the layers above the *Homo floresiensis* fossils for which the site is most famous, domesticated pig and translocated fauna (porcupines, civet cats and monkeys) are associated with pottery and a c. 3,600 BP date (Van den Bergh et al. 2009), while some of the AMH burials on which Soejono focused are now directly dated to the fourth millennium BP (Murti 2018).

Archaeologists based in research institutions in ISEA have also made major contributions to understanding the ISEA Neolithic. Robert Fox, who investigated the Tabon Caves and other cave complexes while working at the National Museum in Manila during the 1960s, strongly believed in developing local expertise. As a result, a succession of Filipino archaeologists, including Alfredo Evangelista, Wilfredo Ronquillo, Victor Paz, Armand Mijares, and Noel Amano, have made important contributions to understanding the Neolithic archaeology of the Philippines. Stephen Chia, who is based at Universiti Sains Malaysia in Penang, has taken a particular interest in Malaysia's Neolithic, which led him to re-excavate the Bukit Tengkorak rockshelter first excavated by Bellwood and Koon (1989). In Indonesia, Truman Simanjuntak and his colleague Bagyo Prasetyo have invigorated research into Indonesia's Neolithic, often working in collaboration with French nationals based in Jakarta. Open-air Neolithic sites that have been investigated include Minanga Sipakko and Mallawa in Sulawesi (Simanjuntak 2008), Benua Keling Lama in Sumatra (Guillaud et al. 2006), and Pain Haka (Galipaud et al. 2016), the only open-air Neolithic cemetery yet documented for ISEA. In addition, a faint signature of Neolithic occupation has been recorded for the Gunung Sewu cave

sites in East Java (Simanjuntak 2002) and Gua Harimau in Sumatra (Fauzi 2016).

Neolithic sites have now been professionally documented virtually across ISEA and in sufficient number to advance some generalizations. One such generalization is a distinction between sites with a material culture that signals a clear disjunction from the mid-Holocene forager material culture, and sites whose material culture indicates continuity (apart from the introduction of pottery).

As for the sites with a disjunctive material culture, the first group includes all of ISEA's open-air Neolithic sites. In addition to the examples covered above, these sites include Dimolit in Luzon (with its traces of a house floor), Edjek in the central Philippines (Bellwood 2017), Telling and Mansiri in North Sulawesi (Simanjuntak 2008; Azis et al. 2018), and Ay PA1 in the Bandas (Piper 2017). The second group includes the Neolithic cemeteries, whether substantial (Niah Caves, Liang Bua, and Pain Haka) or minor, such as Lubang Angin in Sarawak, which persisted as a burial cave into the Early Metal Phase (Datan and Bellwood 1991), and Arku Cave in Luzon (Bellwood 2017). The third group includes cave sites with little, if any, evidence of pre-Neolithic habitation, either because the Neolithic marked the colonization of the area, as was the case for the Batanes Islands (Bellwood and Dizon 2013) or because the cave was unsuitable for habitation prior to the Neolithic. Examples in the latter category include Bukit Tengkorak (Bellwood 2017), Uattamdi in the northern Moluccas (Bellwood et al. 1998), Pondok Selabe 1 in Sumatra (Simanjuntak et al. 2006), and possibly Hoekgroet in Java (Storm 1995) as well as Liang Kaung and Jambu Hilir in Indonesian Borneo (Plutniak et al. 2014). Neolithic industries based on flaking stone have been recorded at some of these sites, but their character is different from local, pre-Neolithic counterparts. Bukit Tengkorak is renowned for its agate microblades and awls and, most notably, chips of obsidian transported from the Admiralty Islands and New Britain located more than 3,000 km to the east. In addition, obsidian transported shorter distances overland dominates the flaked stone at Pondok Selabe 1, and also Bukit Arat (Bonatz 2009) as well as Kamassi and Minanga Sipakko (Angrraeni 2012).

The sites that show continuity of material culture include the most contentious for dating the ISEA Neolithic because pot shards may infiltrate deeper, older deposit and so produce a misleadingly early dating for when pottery was introduced. This is the accepted explanation for rejecting formerly entertained mid-Holocene dates for pottery at Leang Tuwo Mane'e in the Talaud Islands (Bellwood 2017), Ulu Leang 1 in South Sulawesi (Bulbeck 2004), Kimanis and Lubang Payu in Indonesian Borneo (Plutniak et al. 2014), and Uai Bobo and Bui Ceri Uato in East Timor (O'Connor 2015). Bellwood (2017) proposes a similar explanation for questioning the c. 4,500 BP date from Gua Sireh, but accepts this would not work for the c. 4,300 date on an identified rice grain in a pot shard, suggesting instead that the superseded protocols employed to generate that date may be at stake. Similarly, Spriggs (1989) queries the reliability of the Gakushuin Laboratory radiocarbon dates that collectively imply a mid- to late Holocene dating for the ceramic layers at Rabel Cave in Luzon. Certainly, when dealing with sites with pre-pottery habitation, archaeologists are now circumspect about dating the appearance of pottery before the fourth millennium BP, as for instance at Callao Cave and Dalan Serkot in Luzon (Mijares 2007), Agop Atas in Sabah (Bellwood 2017), Liang Jon in Indonesian Borneo (Plutniak et al. 2014), Leang Burung 1 in South Sulawesi (Bulbeck 2004), and Macha Kuru and Lene Hara in East Timor (O'Connor 2015). Particularly on the larger islands, continuity of occupation into the Neolithic is likely to reflect the sustained presence of the original foragers, who obtained Neolithic material culture and farm produce from their Malayo-Polynesian neighbors through trade (Bulbeck 2004; Mijares 2007).

Key Issues/Current Debates

The joint intrusion into ISEA of Malayo-Polynesian speakers and Neolithic material

culture invites the use of historical linguistics to reconstruct the Proto-Malayo-Polynesian vocabulary and thus infer the subsistence and technology of the Malayo-Polynesian immigrants. The reconstructed vocabulary is wide-ranging and includes, inter alia, rice, foxtail millet, taro, greater yam, breadfruit, banana, sago, sugarcane, coconut, pandanus, pottery, adzes, weaving, house, granary, outrigger canoe, sail, dog, domesticated pig, rooster, fishing and hunting equipment, monkey, squirrel, pangolin, dolphinfish, tuna, and bonito. It points to a mixed economy and skills in sailing, pottery production and, at least as far south as Luzon (based on corroboratory archaeological evidence), weaving (Bellwood 2017).

A capacity to grow crops may well have provided the Malayo-Polynesian immigrants with a demographic advantage over the resident foragers but firm archaeological evidence for Neolithic agriculture in ISEA is slim. The Neolithic shell mounds of Magapit, Nagsabaran, and Andarayan on the Cagayan River provide the strongest support with remains of rice dated to 3,000–4,000 BP at all of these sites along with banana phytoliths at Magapit (Hung 2017). Rice phytoliths have also been recovered from the Neolithic levels of Gua Sireh and Kamassi and some of the Neolithic pottery from Niah Cave is tempered with rice (Bellwood 2017).

Taro, presumably cultivated, and various possibly cultivated tubers and pulses have been identified from the Neolithic levels of Leang Burung 1 (Paz 2004). However, any Malayo-Polynesian association would have been at best indirect in view of the many important tree and root crops in ISEA, such as bananas, sago, sugarcane, and the greater yam, that were probably first domesticated in the New Guinea region and then introduced to ISEA. Historical linguistic evidence suggests that they were encountered by early Malayo-Polynesian speakers during their expansion southwards, and that small-scale agriculture was accordingly practiced in ISEA prior to the Neolithic (Donohue and Denham 2009; Blench 2012).

Evidence for domesticated animals in Neolithic ISEA is similarly complicated (Piper 2017). Two sources for domesticated *Sus scrofa* pigs have been identified: Taiwan as the homeland of the "Lanyu" pigs that were introduced into the Philippines, and MSEA as the source for the "Pacific clade" pigs that were transported through the islands of Indonesia into Oceania. Dogs too probably had dual origins, in Taiwan and MSEA, with the faint possibility of a pre-Neolithic dispersal of the lineage of dogs ancestral to Australia's dingoes. Chickens are difficult to assess because they are common in Neolithic contexts in MSEA and Oceania but as yet unidentified in the intervening islands, which does not however rule out a Philippine source for Oceania's chickens. Intriguingly, remains of the *Sus celebensis* "warty pig" of Sulawesi have been dated back to at least the Neolithic at Liang Bua, but this may reflect translocation of wild fauna rather than domestication of this species, similar to the Neolithic faunal translocations to East Timor. Certainly, south of the Batanes Islands (Bellwood and Dizon 2013), hunted rather than domesticated animals appear to dominate Neolithic faunal assemblages in ISEA, as for instance at Hoekgrot (Storm 1995), Liang Bua (Van den Bergh et al. 2009), and Kamassi and Minanga Sipakko, where a minor component of translocated deer and porcupines is also in evidence (Angrraeni 2012).

Osteometric evidence is mixed for discontinuity in ISEA between pre-Neolithic "Australoids," characterized by long, robust skulls, and large teeth, and Neolithic "Mongoloids" characterized by broad, gracile skulls, and small, differently proportioned teeth. A Neolithic burial from Nagsabaran reveals a long skull shape while its dental measurements (along with those of the Bunun of Taiwan) place it an intermediate position between Australoids and Mongoloids (Oxenham et al. 2016). A broad skull shape and small to moderate tooth size are documented for Java's Neolithic burials at Song Keplek and Hoekgrot, in contrast to pre-Neolithic Java skulls (Bulbeck 2015), although the Hoekgrot skull is robust for a female (Storm 1995). At Niah Cave, the Neolithic teeth are smaller and differently proportioned compared with the pre-Neolithic teeth, indicating population discontinuity (Bulbeck 2015). In contrast, at Gua

Harimau, there is less evidence from osteometric (or ancient DNA) analysis for pre-Neolithic/Neolithic discontinuity than there is for discontinuity between the pre-Neolithic-cum-Neolithic and the Early Metal Phase inhabitants (Matsumura et al. 2016, 2018).

In addition to the Taiwan–Philippines connection noted above, there is now considerable evidence for a separate introduction of the Neolithic from MSEA into western ISEA. MSEA as the identified source for the "Pacific clade" pigs and as a likely source for one of ISEA's two dog clades has been noted above. Further, study of early Neolithic pottery indicates two distinct traditions, with an apparent interface zone in central-eastern Borneo (Plutniak et al. 2014). One, clearly derived from Taiwan, is the red-slipped ware of the Philippines, Sabah, and Sulawesi, mostly plain but otherwise decorated predominantly with dentate stamping (Bellwood 2017; Azis et al. 2018). The second tradition, for which MSEA is the likely the precursor (Bellwood 2017), involved use of a paddle (often carved or cord-wrapped) to impart decorations, as documented for Bukit Arat (Bonatz 2009), Pondok Selabe 1 (Simanjuntak et al. 2006), Gua Harimau (Bellwood 2017), Gua Sireh (Datan and Bellwood 1991), Niah (Lloyd-Smith et al. 2013), and Nangabalang and Liang Kaung in central Borneo (Plutniak et al. 2014). Genetic studies on present-day ISEA populations clearly point to approximately contemporary population dispersals from MSEA into western ISEA, and from Taiwan into the Philippines and then across ISEA (Cox 2017). Analysis of the languages of western ISEA has also identified a widespread stratum related to the Austroasiatic languages of MSEA, including Dayak languages near Gua Sireh with its anomalously early Neolithic dating (Donohue and Denham 2009; Blench 2012). Thus, whether or not the spread of Malayo-Polynesian across eastern ISEA involved immigrant farmers supplanting the indigenous foragers, its spread across western ISEA appears to have more involved a language switch by communities that were already Neolithic. A likely motivation to cover both cases would be a founder ideology whereby ambitious individuals, intent on being glorified as an ancestor, ventured off to establish new communities (Blench 2012).

The time is past for grandstanding on whether the ISEA Neolithic was founded on the migration of farming communities or the maritime movement of useful technologies and resources, and whether its cultural matrix mainly reflects introduced concepts or the incorporation of pre-Neolithic knowhow. All of these were important, and speculation on their relative importance obfuscates an appreciation of their complementary but diverse roles in different situations. For instance, extended burials appeared in ISEA with the Neolithic but were interred cheek by jowl with the flexed and bundle burials also identified in pre-Neolithic contexts (Lloyd-Smith et al. 2013; Galipaud et al. 2016). Similarly, the successful adaptation of Neolithic communities to new environments would have relied on tapping into local foragers' knowledge on resource distribution and pathways through the forest, as expounded by Bulbeck (2004) for South Sulawesi.

International Perspectives

The ISEA Neolithic is of international interest for its late beginnings in comparison with the onset of the Neolithic in the surrounding tropics and subtropics of MSEA, Taiwan, and New Guinea. The evidence covered above indicates that ISEA was a recipient of crops from both Taiwan and New Guinea, and domesticated animals, pottery, and languages from both MSEA and Taiwan. These multiple sources are a reason why the culture history of the ISEA Neolithic has been so difficult to unravel. On the other hand, a passive role of ISEA in the development of its Neolithic is also disproved by the evidence at hand. Pre-Neolithic knowhow helped shape the ISEA Neolithic, and the number of mammal species translocated across ISEA, presumably to improve the returns from hunting, exceeded the number of introduced domestic animals. Also, as discussed by Bellwood (2017), Neolithic ISEA appears to have been the nursery for the Lapita culture that introduced the Neolithic into the islands in the east of New Guinea and gave rise to the Polynesians.

Future Directions

An understanding of the cultural history of the ISEA Neolithic will not be complete until attention is paid to Neolithic cultural innovations within the region that subsequently spread across ISEA. An example is the "Austronesian Painting Tradition," based on sketches (usually in black) on rock surfaces, which has its most concentrated expression in Sulawesi, southeastern ISEA, and Vanuatu (Hakim et al. 2018). Where charcoal can be identified as a component of the black pigment, the artwork is amenable to Carbon-14 dating, which would allow the source of the tradition to be identified and its dispersal routes to be traced. Another example is pottery motifs of confirmed Neolithic antiquity in ISEA which cannot be directly derived from MSEA or Taiwan, and whose similarities between pottery assemblages may illuminate spheres of contact within ISEA.

An emerging priority is anthropological investigation into the beliefs and social systems of ISEA Neolithic communities rather than a narrow focus on culture history. Galipaud et al. (2016) discuss the ideological implications of the Neolithic innovations at Niah and Pain Haka of burials in or associated with jars, and disarticulation of skulls from the postcranial skeleton, as also documented at Teouma in Vanuatu. However, as yet there has been little study of whether social stratification emerged during the Neolithic, a topic that would be amenable to investigation based on the rich mortuary assemblages and wide variety of burial practices now documented for ISEA cemeteries.

Island Southeast Asia: Rock Art

Jean-Michel Chazine
AMU-CNRS-CREDO, Marseille, France

Introduction

Until the late 1990s, Indonesia and more generally Island Southeast Asia were rarely quoted as rock art locations in the general scholars' literature describing – or trying to explain – the development of art, from prehistoric to recent times. However, important rock art did exist and had in some places been surveyed, sketched, or mapped, by the end of the nineteenth century (Fig. 1). This is the case for instance in part of the northwestern coastline of West Papua, which presents kilometers of huge painted limestone cliffs. Also in Timor as much as in the small island of Kei Kecil, caves or cliffs with paintings had been observed for some time. Some miles toward the west, the island of Sulawesi contains also at least three places far away from each other with important and significant paintings.

Island Southeast Asia: Rock Art, Fig. 1 Island Southeast Asia, location of main rock art. (@Ph. Delange - 2004/ J.M. Chazine/Kalimanthrope 2009)

A similar situation, although happening later, i.e., after WW II, is the great mouth of Niah Cave (in the northern Sarawak province of Malaysia), a gigantic and actually most important site for the archaeology of the region with a backyard gallery of paintings linked to funerary process (Solheim II 1983). Less important but as significant are the figures painted in a large gallery besides Gua Sireh Cave, also in southern Sarawak (Bellwood and Datan 1993). The latter were nevertheless considered as not very ancient, with an estimated age of up to 2,000 years old only.

All of these paintings, although more or less locally recognized, did not appear as important as those which had already been identified and displayed worldwide which are those by the Australian Aborigines.

And the others, mere charcoal sketches, which had been only quoted in South Kalimantan or discovered later in the south Philippines (Palawan island), appeared of too little importance to have great weight in the appreciation of rock art in Island Southeast Asia.

Definition

Apart from the simple aspect of paintings, their representations, styles, and contents, which would explain that relative disdain, the age corresponding to these paintings must be considered. Australian Aboriginal paintings associated with a community, which at the time were considered by the majority of the world as almost sole surviving from the prehistory, were attracting enough and could be nearly compared with the first attested prehistoric paintings from the main European Franco-Cantabric caves.

Historical Background

Knowledge of actual communities from Southeast Asia was far from well-known and their prehistory even less. Therefore, it is not surprising that their rock art is found difficult to elicit the slightest interest. Moreover, for Indonesia, the first specialists were convinced that in any case, it would have

been the Aboriginal influence, which would have spread from Papua through Timor and Sulawesi, being stopped by the Wallace Line separating the east from the west. At that time, no painting at all had been observed in Java, Sumatra, as much as in the Indonesian Borneo, i.e., the Kalimantan provinces nor continental Malaysia, Philippines, or Thailand. Therefore, Wallace Line could be considered also as a cultural frontier for a retroverse influence of a specific Aboriginal practice (Heekeren 1958).

Recently some geometric red paintings presenting seemingly ethnic designs have been observed in Harimau Cave, South Sumatra (Simantjutak 2011). Their scarcity does not change the general absence of "archaic" paintings in central and western Indonesia.

Although in 1988, a French team of cavers observed an unknown charcoal panel in Liang Kaung in the central Müller Range (Fig. 2), when trekking across Borneo from west to east, these charcoal drawings were similar in conception to the other charcoal designs found in the area.

Yet, the surprise was complete when in 1994, a Franco-Indonesian team, linked to the previous one, venturing into the deep karst of East Borneo discovered the very first paintings rather ancient if not completely "archaic." Of course, the question of the age of these supposed prehistoric paintings has been debated from the very beginning of their study and still occurs. Although dating processes have enhanced their possibilities and results, many cases are still resistant to direct dating by lack of organic stuff, forcing indirect estimations.

In the case of that really new and somehow puzzling discovery, it is the presence of hand stencils (also called "negative hands") which would attest of the antiquity of their authors. Almost everywhere in the world, stenciled hands are present, and as they appear from the very beginning in the oldest attested ornate caves or shelters (up to 30,000 year BP), they are considered as clues for a relative antiquity.

Island Southeast Asia: Rock Art, Fig. 2 Liang Kaung (west Kalimantan): charcoal drawings. L.H. Fage sketchings

In fact this assumption has to be nuanced because there are also clues of relatively recent if not contemporary examples of hand stenciling practices and not only in Australia. That kind of practice would then be more that one of a cultural stage or a particular cosmogonic relation with the world than a real proof of dated antiquity. Nevertheless both considerations may complete each other, and if they can be isolated from others, they may induce differences. This is the case for the East Kalimantan paintings, which until now are the only ones which present hand stencils all over the whole Borneo Island.

From that discovery and once assumed that a rock art did exist in that part of Borneo, further surveys completed these primary observations, and up to more than 30 ornate caves have been checked (Fage and Chazine 2010). Including geomorphologic observations, it was obvious that all the painted caves were in the highest levels of fossilized galleries, in the most remote and near-unreachable places, and far from the usual treks of remaining local hunters and bird nests' collectors. Moreover, no occupation remains could be found in these ornate caves. Archaeological evidence of final Pleistocene dwellings could be found (and as possibly excavated) only in the basements of cliffs or, more rarely, in the first level of galleries while a calcite veil covering hands stencils was nevertheless already dated over 10,000 years BP (Causse et al. 2003).

Thus, it became interesting and even necessary to check if comparisons, similarities, obvious differences, and contents would be worthwhile for a general overview of the rock art in the region. Communications and publications in different congresses in order to get subsidies for research enhanced a larger interest for Borneo's prehistory and more generally for Indonesian rock art.

Added to that is the fact that a particularly high number of stenciled hands have been checked (over 2,000 altogether with near 1,000 in 4 caves only) where they were sometimes applied on ceilings (Fig. 3), up to 8 and even 14 m. Another exceptional fact is that some of these negative hands are linked together and in many cases are also overpainted with different motifs (Fig. 4). Moreover, there are two cases where there are only and numerous stenciled hands (over 2 × 130 of them). This latter occurrence led thus to consider differently the practice of hand stenciling and tries to elaborate some practical explanation to that specific practice and materialization.

In fact, the possible deciphering of the hand stenciling principle, may make it possible to apply it to the different cases encountered in the area and more precisely to the Indonesian examples.

The case of the twin caves called Gua Masri I and II (from the guide's name) containing only hands and absolutely no other motifs would be the "Rosetta Stone" to express the function (at least in Borneo's cases) of hand stenciling. Considering that the author(s) did not need to "complete" the painted panels with other motifs, it may be deduced that this action would have been sufficient and would have completely answered their expectations. Apart from all the explanations, which have been proposed since the beginning

Island Southeast Asia: Rock Art, Fig. 3 Decipheration of male/female hands stencils from the Gua Ham's frieze, showing a strict sexual division of space, established in using Manning's ratio (Manning 2002)

of rock art studies in the early twentieth century and which are not convincing in Borneo's cases, there is at least one clue, which would fit with that context: the ethnographic observation of some of the healing process still practiced in many traditional cultures, with the applying of hands, the breathing of revitalizing energy, and the spitting of magico-therapeutic substances, is nothing but identical to the hands stenciling process on the caves walls.

Island Southeast Asia: Rock Art, Fig. 4 The Tree of Life (or Family?) representation using hands stencils in Gua Tewet' shelter. TEW017, Borneo 1999. (Photo: Luc-Henri Fage, Le Kalimanthrope)

As it has recently been proposed, a shamanic environment may have been in action in the ornating of prehistoric caves (Lewis-Williams 1993; Clottes 2004), thus healing process would have been active in the same and single way. Of course, considering the very difficult access to the Borneo's ornate caves, it would have been an indirect procedure, a simulacra or an allegoric way of mastering forces or powers, would they be from ancestors or Nature's spirits. Pushing the hypotheses further, it became possible, once knowing, then using what is called Manning's ratio, which is able to decipher men and women's hands from the length ratio between forefinger and ring finger to find also women's hands (Fig. 5) in the different panels of caves from different parts of the world (Chazine and Noury 2009). Throughout the world, healers are either men or women and this observation fits with the display of deciphered hands, which have been observed in the ornate caves up until now.

Island Southeast Asia: Rock Art, Fig. 5 Analysis of the sexual identity of artists who produced the Masri II panel, using @Kalimain1.0 from L.H. Fage's picture and computer reconstruction

And this is the case for Indonesian rock art where each site of minimal importance contains at least a couple of hand stencils.

These converging clues provide a kind of basic lecture grid. Once it is admitted that what is called rock art would have corresponded to some specific rituals practiced by still animist communities, for whom schematically, the whole of nature with its powers includes and also is related to all the human condition, one is able to prepare a more acute model to explain the different cases encountered.

Related to this latter point is the fact that stylistic expressions are present. In some cases, they are materially visible, like overimpressions, scrapings for new designs, or clear changes, and move toward more realistic and expressive figures. This is supposed to be linked to a very important and deep change, which occurred with the arrival of the Austronesian migration, 5,000 to 3,000 years BP, which spreads all over the Indo-Pacific area. Bringing new technologies, new beliefs, and thus new funerary practice, they also brought new aesthetic expressions (Bellwood 1997). It seems that in some cases, it drew a halt to rock art expressions, while in others, it provoked some significant changes and lasted, but slightly transformed, until the end of the pre-European periods.

When the two influences became intermixed, it is often difficult to separate the different periods, and sometimes it seems that the Austronesian has itself also adopted a pre-Austronesian core and adapted it to its needs.

This may be observed in the different sites holding rock art, which are to be found from eastern to central Indonesia, i.e., West Papua, Timor, Moluccas, Sulawesi, and Borneo.

West Papua: The northwestern shores of West Papua have been visited since the mid-sixteenth century for the traffic of the West Indies Company, and many navigators or visitors have been already able to see some paintings along the cliffs of its northern tip, i.e., mainly the McCluer Bay (now Berau Bay) and its surrounding capes, small archipelagoes, and tributaries of rivers. But in fact, it is not before the German Frobenius expedition in 1937–1938, and thanks to Röder's engagement in surveying it as completely as possible that the real riches of its rock art heritage could be appreciated (Röder 1959). Hundreds of sites containing altogether thousands of paintings or motifs have been surveyed and checked. As the publication of the final report had to be postponed until after WW II, not many could appreciate or evaluate the importance of his observations, and one must practically wait until a UNESCO project led to the launching of a book (Delanghe and Arifin 2004) presenting as many as possible pictures and descriptions of that impressive although sometimes strange core of rock art.

Although the first enquiries were made before WW II, with still traditionally living communities, not much ethnographic data could be gathered, giving thus the status of archaeological remains to these paintings and obliging hypothetic assumptions concerning their age, interpretations, functions, and authors.

Most of the paintings that appear inside pre-Holocene sea wave groove galleries were dug in the cliffs 3–8 m above the mean sea level (msl). Sometimes paintings have been executed as high as 30 m or so and thus are now unreachable. In whole, it is still difficult to relate them to actually living communities, which in some places do not even recognize them as theirs, themselves affirming their somehow foreign origin. This latter point relates to the spread of the Austronesian impact over the whole Insulinde has permitted to some researchers to develop hypothesis linking the paintings to an Austronesian original core (Ballard 1992), using between others convincing linguistic clues. The diversity of situations cannot be restricted to one single explanation and shows that conditions of development of the painting process associated with differentiating rituals happened also differently all along more or less pre- and protohistoric periods.

Although it is difficult to produce firm results for this mass of painted motifs (Delanghe and Arifin 2004: 59–225), some main directions of expressions may be outlined.

Key Issues/Current Debates

First, the most common rock art is comprised of hand stencils that are similar in their diverse representations (more or less with the arm or the fingers, i.e., so-called mutilated, corresponding also effectively to a vanishing Papuan tradition forcing widows to cut out one or more of their phalanx). More seldom are stenciled fishes, lizard, leaves, feet, and more or less recognizable artifacts like combs, boomerangs, sticks, masks, headdresses, crescents, or ornaments (supposed to be a moon representation).

Second, many fishes some of which are stenciled (the biggest local fishes like tuna, sharks, or barracuda) are represented with the particularity to be in vertical position, which is a quite unnatural and obviously a deliberate symbolic choice.

Then anthropomorphic figures, which depending of the site, bear different names that could correspond to a variety of ancestors, spirits, or deities. The most known and leader ancestor of most of the local communities is the Matutuo figure with a general shape of a lizard with a human face and sometimes a conic headdress. Near these representations are tattoo designs, which also have a strong correspondence with ancestors and kin groups.

Also present at almost every site are what is for modern observers, undeterminable/undetermined more or less complex circular, concentric, curvilinear, or even simple geometric figures. These probably correspond to symbolic representations and thus to possible ritual or ceremonial purposes.

At a distant and by side notice, it must be quoted that glyphs from Sosorra-weru designed by Röder (Delanghe and Arifin 2004: 74) have since disappeared. They would nevertheless correspond to some meta-logs of the long travel of Tanawa-Maui, quoted by Erathosten 200 C.E. (Fell 1975).

Now that Indonesian rock art has begun to demonstrate its importance, there is no year and no place where a new set of more or less ancient paintings or drawings would not be observed. For instance, 200 km away in the western vicinity of Berau Gulf area, southeast of Misool Island, a new complex of painted panels on karstic cliffs dropping straight into the sea were recently discovered and shortly first surveyed (Chazine 2011). It has since been largely completed and provided a larger set of figures (Oktaviana et al. 2018) and even possible underwater excavations (Shinatria and Yarista 2019).

Although similar motifs (mostly vertical large fish, stenciled hands and fish symbolic circular designs, or maze drawings) are present (Fig. 6), some motifs are unique. In particular, one large panel with a stenciled "Yoni" (another one was identified by Walsh in Carnarvon Gorge, Australia) with a negative hand besides identified as feminine, then five stenciled round mats or basketry sets (Fig. 7). But what was even more interesting is that it could be deduced that the locations of the painted panels on the cliffs had been exclusively selected for apparent geomorphological reasons. Practically paintings appear only on large cliffs in association with a large colored (from yellow to brown) strip coming out – or into – a more or less large cave, cavern, crevice, or dark hollow. Whatever the surrounding

Island Southeast Asia: Rock Art, Fig. 6 One of the numerous panels from Misool sunken karst (Raja Ampat-Indonesia) representing marine fauna

Island Southeast Asia: Rock Art, Fig. 7 Panel with a unique "Yoni" and some circular openwork basketwork stencils from Misool's karst (Raja Ampat-Indonesia)

state of the rock might be, there are – or not – paintings if these three parameters linked together are, or not, present. Therefore, the precise choice of these places seems established and would thus permit some interpretations. As suggested before, painting practices were probably a complementary part of the expressions of rituals and ceremonies, be they shamanic, initiatic, or healing procedures. Here, the analogy between the natural geologic aspects of the cliffs suggests associations with chthonian forces, feminine wombs, and thus fecundity or fertility longings. Moreover, this particular area is remote from the main island (more than 1 h dugout canoe), isolated, without possible settlement facilities. Further surveys have shown that if these combined parameters were present but disassociated there was no painting, indicating a very specific choice for the sites, which moreover cannot be seen one from the other.

International Perspectives

Using these interpretative clues for other rock art sites may provide some help in deciphering the original grounds for such a large variety in individual designs and common if not universal, expression of trends and leanings.

Figures and designs, which have been observed and studied in Timor, are basically similar to those from Berau Bay and its vicinity, but in many points they provide more complex figures, which following the local "sacred site" keepers' assertion should remain secret but would be somehow equivalent to the Matutuo principle: a complex figure of a supra-deity overwhelming the whole world. Significantly for dating assumptions, there are almost no negative hands, and many paintings present realistic moving human figures or in contrary very simple S shape or reduced to broad large lines. The presence of some boats surrounded by men carrying artifacts: tools or weapons, dance, or ceremonial sticks (?), and obvious narratives, which are clearly represented, would correspond to rather recent periods.

Future Directions

Thus, the dispersal and variety of paintings and representations provide a clear image of the complexity of human settlements over the time on the different islands of the archipelago. Although clues exist of a very ancient peopling (up to 30,000 BP) occupying the islands (O'Connor 2003; O'Connor et al. 2018), it is not definitely clear when or if the first settlers made paintings. What is sure is that many of other last Austronesian newcomers did practice – and still do – secret rituals associated with paintings. Contemporary ethnographic data could provide stimulating clues for understanding how rock art could have been linked to sociocultural practices in the past.

A past, which has been strongly enhanced since the datings of calcite layers enclosing hands paintings, first in 7 Maros Sulawesi's caves (Aubert et al. 2014, then in Marang River caves in East Kalimantan (Aubert et al. 2018), these latter dated from circa 13–15,000 to 40,000 years BP up to 52,000 years BP. A quasi revolution in the ISEA prehistory of Rock Art! First because it provides a completely changed glance upon not only the general prehistory of the whole Island SEA but secondly also a new space for research concerning Rock Art expressions, chronologies, genetics, and anthropological interpretations (Taçon et al. 2014). If definitely confirmed, and up to now, the East and North Kalimantan's Rock Art has suddenly emerged within the oldest figurative and aesthetic human expressions of the world! And Misool Island has become a determining target in the peopling process of ISEA. Therefore, the original haphazardous discoveries on rock art in Kalimantan, then in Misool, have provoked an unexpected and highly stimulating movement of research and discoveries, which is bearing large and dazzling prospects.

Isotope Geochemistry in Archaeology

Ian Moffat
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia
Research School of Earth Sciences, The Australian National University, Acton, ACT, Australia

Introduction

Isotope geochemistry is an important scientific technique that has made a significant contribution to archaeological research. Isotope techniques measure the relative abundance of a number of nuclides of the same (or derivative) element as a means of investigating a variety of natural processes. Both stable (H, O, C, N, Ca, Sr, Cu, Pb, S) and unstable (U, Th, K, Ar) isotope systems are analyzed as part of archaeological investigations.

Isotopes (often referred to as a nuclide in the singular) are variants of a particular element, which share the same number of protons but have varying numbers of neutrons. Isotopes are referred to as stable or unstable, depending on whether they undergo radioactive decay. Some nuclides are primordial, meaning they have existed since the beginning of the universe, while others are the product of the decay of other elements. Isotopes of the same element generally share the same chemical behavior.

Stable isotopes can be applied to studying a variety of processes with their applicability to specific problems depending on the mechanism by which one nuclide becomes naturally enriched or depleted. The basis of the application of some stable isotopes is that the variation in their atomic mass leads them to behave differently during processes such as evaporation, precipitation, freezing, photosynthesis, and incorporation into the body. Another approach is based on taking advantage of the varying abundance of some stable isotopes within different geological units to allow

proveniencing of various materials. This can only be achieved if the isotope ratios remain unchanged after incorporation into the sample.

Unstable isotopes are most commonly used as a geochronological tool for establishing the age of materials such as organics, calcium carbonates, and igneous rocks. Unstable nuclides that have either too many or too few neutrons spontaneously transform by beta decay, alpha decay, or spontaneous nuclear fission. The decay speed can be calibrated to time and is usually expressed as a "half-life." On the basis of a known decay rate and original abundance ratio, the comparison of the relative abundance of a stable nuclide to an unstable nuclide can provide an age estimation of the material studied. In the case of radiocarbon dating, the abundance of ^{14}C in the sample is compared to modern levels of ^{14}C.

Isotope analysis can be performed directly on archaeological materials or on geological materials to provide a context for archaeological sites. A particular advantage of using isotopic methods in archaeological investigations is that it provides quantifiable information that can be compared to the material culture record.

Definition

Isotope geochemistry is the measurement of the relative abundance of different species of the same element that have the same number of protons but varying numbers of neutrons. A wide range of elements and materials can be analyzed to provide insights into age, diet, mobility, climate, and provenience with important implications for archaeology.

Key Issues/Current Debates/Future Directions/Examples

A wide (and increasing) number of isotope systems can be applied to archaeological questions. This entry introduces each isotope system that has been applied in archaeological research and discusses the rationale for its use.

Hydrogen has two stable isotopes: ^{1}H and ^{2}H (often known as deuterium). Isotope results for this element are usually reported as δD that represents $^{2}H/^{1}H$ compared to the Vienna Standard Mean Ocean Water standard. This method, which is suitable to the analysis of collagen, has been used to determine paleoclimate (Leyden et al. 2006) and diet (Reynard and Hedges 2008) for archaeological samples. This technique works on the basis that hydrogen isotope ratios of precipitation vary according to climate and geography. Hydrogen in plant tissues, particularly from shallow-rooted plants, is generally sourced from leaf water derived from growing season precipitation. There is no fractionation of hydrogen during water uptake by terrestrial plants and the δD composition of herbivore tissue correlates to that of their diet, providing a time-averaged composition over their lifetime. δD values are fractionated with trophic level, with an increase of 30–50‰ from herbivores to omnivores and 10–20‰ from omnivores to herbivores, and are not influenced by other parameters, such as those which influence $\delta^{15}N$ (Reynard and Hedges 2008). As a result, this method can be used for sample provenience (using existing maps of δD), to examine changes in precipitation regime or to measure trophic level.

Oxygen has three stable isotopes: ^{16}O, ^{17}O, and ^{18}O. Results are commonly reported as $\delta^{18}O$ which reflects the ratio of ^{18}O to ^{16}O compared to a known isotope standard such as Standard Mean Ocean Water. Oxygen isotopes are fractionated by a variety of processes with the heavier ^{18}O being preferentially precipitated or frozen and the lighter ^{16}O being preferentially evaporated. Oxygen isotope analysis of tooth enamel can be focused on the oxygen atoms from either the phosphate or carbonate portion, although phosphate is traditionally favored as it is considered more resistant to post-burial diagenesis.

The oxygen isotope analysis of marine carbonates or ice cores allows the global ice volume to be estimated through time. This led the Quaternary to be divided into Marine Isotope Stages, which provide a broad framework for climate variation between glacial and interglacial periods. These changes are driven by Milankovitch cyclicity, in which the eccentricity, obliquity, and precession of the Earth's orbit vary on a regular timescale.

The Marine Isotope Stage changes have had a significant effect on plant, animal, and hominin biogeography. The oxygen isotope composition of mammal tooth and bone reflects the $\delta^{18}O$ of ingested water and macronutrients in food (Sponheimer and Lee-Thorp 1999). Ingested water has a composition similar to meteoric water, which is sensitive both to temperature and precipitation. The water in shallow-rooted plant stems and roots reflects meteoric water, although the value from leaves is enriched in ^{18}O. The effect of mammalian diet and physiology on isotope composition is poorly understood, although the relative proportion of oxygen derived from food or water may be significant. Overall, oxygen isotope analysis is a very commonly applied technique in archaeological research that has frequently been used as a proxy for climate or diet.

Carbon isotopes, reviewed by Lee-Thorp (2002), can be applied to archaeological biogenic minerals to determine the nature of vegetation included in diet. The method works on the basis that ^{13}C is strongly discriminated against during photosynthesis; however, the degree to which this occurs varies between different photosynthetic pathways. The C3, C4, and CAM photosynthetic pathways have distinctly different levels of ^{13}C, with C4 plants ranging between 9‰ and −16‰ and C3 plants ranging between −22‰ and −34‰. C4 plants are principally grasses which are predominant in areas with higher levels of solar radiation. The carbon isotope composition of biominerals such as bone, teeth, and shell will reflect the plant material in diet. Carbon isotopes have also been applied to determine the proveniencing of archaeological marble. Carbon isotope composition may also reflect the degree of marine resources within an individual's diet, as there is a significant difference in the isotopic composition of dissolved ocean bicarbonate and atmospheric carbon dioxide which is reflected in plant values (Richards and Trinkaus 2009).

Radiocarbon dating, a derivative of carbon isotope analysis, measures the amount of ^{14}C (which has a half-life of 5730 years) in a sample and compares this value to the level in modern systems. The dating technique, which is suitable for organic materials, is ubiquitous in archaeology due to its relatively low cost and accurate and precise results. More effective sample pretreatment methodologies and the use of accelerator mass spectrometry instruments has recently allowed a wider range of materials and smaller samples to be analyzed. The principal disadvantage of this method is that the amount of ^{14}C becomes too small for statistically robust analysis after ~40,000 years. Dates from radiocarbon are usually presented as "years before present" (BP) in which 1952 is taken to be present or as "calibrated years before present" (Cal BP). Calibrated years before present recognizes that the level of atmospheric ^{14}C has varied over time which is adjusted using a calibration curve constructed based on samples dated by other methods, such as dendrochronology or stratigraphy.

Nitrogen has two stable isotopes, ^{14}N and ^{15}N, the analysis of which in terms of archaeological studies is reviewed by Hedges and Reynard (2007). ^{15}N is progressively concentrated at higher trophic levels as shown by an increase in $\delta^{15}N$ values of 3–5‰ for each iteration. Nitrogen may also provide insights into weaning behavior (Schurr 1998). Bone and teeth are amenable to analysis for nitrogen isotope composition. There are however a number of complicating factors, including effects from temperature and aridity, which mean that nitrogen isotope results must be interpreted within geographic context.

Calcium isotopes, reviewed by Reynard et al. (2010), are utilized in archaeological investigations on the basis that they reflect some parameters of an individual's diet including trophic level and level of dairy consumption. Calcium isotope results are usually reported as $\delta^{44/42}Ca$ or $\delta^{44/40}C$. There appears to be a significant fractionation between diet and bone but little fractionation between diet and soft tissues.

The application of strontium isotopes as a provenience tool in archaeology is summarized by Bentley (2006). Strontium has four naturally occurring isotopes including ^{84}Sr, ^{86}Sr, ^{87}Sr, and ^{88}Sr of which the relative abundance of these isotopes is invariant and they are essentially stable on archaeological time scales. The analysis of the strontium isotope composition of archaeological

I

materials can provide important information about the mobility of a range of mammals, including humans. The basis of this method is that, prior to any post-burial diagenesis, the Sr^{87}/Sr^{86} ratio of bone and teeth reflects the geological environment from which food and water were sourced while these biominerals were forming. Teeth are particularly amenable to tracing the geographic origins of humans as they mineralize during the first 12–13 years of life and do not subsequently change strontium composition after this time. Strontium isotope analysis can be used to determine if individuals are local or nonlocal by comparison to the isotopic composition in and around their burial location. In order to quantify the extent of faunal mobility, the strontium isotope composition of biominerals from fossil samples needs to be compared with a regional map of values obtained either from local faunal material or from analysis of the bioavailable component of strontium from plants, regolith, or bedrock. Knudson et al. (2010) recently introduced the use of $\delta^{88/86}Sr$ as a measurement of trophic level, on the basis that ^{86}Sr is preferentially incorporated into biological systems.

Copper isotopes have been infrequently utilized in archaeological research; however, potential exists for this method to be utilized as a tool for metal provenience studies (Gale et al. 1999). The stable isotopes ^{63}Cu and ^{65}Cu are usually measured relative to the copper isotope composition of the NIST SRM 976 standard and are reported as $\delta^{65}Cu$. Copper isotopes have not been widely utilized in the past because of the challenge of overcoming problems of incomplete ionization using traditional TIMS instruments, a short coming made redundant by the use of plasma source ionization and multi-collector instruments. Copper isotopes (in combination with iron isotopes) have been used in archaeological bone to discriminate between sexes, on the basis that male bone iron is depleted in ^{56}Fe and enriched in ^{65}Cu relative to female (Jaouen et al. 2012).

Lead isotopes, reviewed by Stos-Gale and Gale (2009) are used as a provenience tool in archaeological investigations. Four stable lead isotopes exist (^{204}Pb, ^{206}Pb, ^{207}Pb, ^{208}Pb) of which all except ^{204}Pb represent the ultimate product of element decay chains from uranium or thorium. The ratio of these isotopes varies between ore bodies and is not affected by anthropogenic processing, allowing them to be used to define the source of archaeological metals. Lead isotope ratios are most commonly reported as $^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$, and $^{208}Pb/^{204}Pb$. Lead is present in a range of archaeological metals including silver, copper, bronze, and brass. Lead may also substitute for calcium in biominerals such as teeth, bone, and ivory with its composition reflecting the isotopic composition of the geological environment where these materials formed.

Sulfur isotopes, reviewed for archaeological applications by Richards et al. (2003), provide information about both the provenience of biominerals and the relative contribution of freshwater and marine materials to diet. There are four stable isotopes of sulfur (^{32}S, ^{33}S, ^{34}S, ^{36}S), and archaeological investigations usually report measurement of the two most abundant isotopes (^{32}S and ^{34}S) as $\delta^{34}S$ with reference to the meteorite standard Canyon Diablo Troilite. The $\delta^{34}S$ of bedrock locally, in combination with rivers and precipitation, controls this value in soil and water and hence plants and animals. The offset between sulfur source and isotopic composition in consumer is very small. There is a significant variation between $\delta^{34}S$ values of marine (+17‰ to +21‰) and terrestrial (−7‰ to +8‰) plants (Privat et al. 2007).

The uranium series technique (which utilizes the isotopes ^{234}U, ^{238}U, and ^{230}Th) is used to date both biological and geological calcium carbonate materials. This technique can provide minimum ages for samples up to an upper limit of ~500,000 years. The basis of this method is that carbonate materials are free from ^{230}Th when formed; however, it will accumulate over time due to the decay of uranium. As ^{230}Th is itself unstable, it will also decay until dating is no longer possible when these isotopes reach secular equilibrium. U-series dating has been widely applied to "closed system" samples such as corals and speleothems in which uranium is present at the time of formation and has also been used for "open system" biominerals such as bone or teeth which contain no premortem uranium. Open system samples are particularly prone to

postformation accumulation of ^{234}U, which is enriched compared to ^{238}U in surface waters and groundwaters. The use of laser ablation systems allows domains of different ages to be located with spatially resolved analysis in the same sample, which have been demonstrated to yield very heterogenous age results for open system samples (Grün et al. 2008). Uranium series can also be used to enhance the accuracy of electron spin resonance dating of tooth enamel by constraining the uranium uptake history of these samples. This approach can dramatically improve the age estimations of this method, particularly in samples with high uranium concentration (Grün et al. 1988).

The K-Ar/Ar-Ar technique is used to date igneous rocks, with a particularly focus on tuffs in archaeological investigations. Unstable ^{40}K, which decays with a half-life of 1.2×10^{10} years to form ^{40}Ar, is abundant in volcanic minerals and glasses. All argon is excluded from the samples by high temperatures associated with igneous processes, and so, all ^{40}Ar present in these minerals must derive from radioactive decay. This argon cannot escape from the crystals as long as the sample is not reheated. In K-Ar dating, the relative abundance of ^{40}K and ^{39}Ar is measured directly, and in Ar-Ar dating, neutron activation is used to form ^{39}Ar by neutron capture on ^{39}K. The extension of this method beyond the limits of radiocarbon and the presence of many tuffs have made this technique important for determining the chronology of the East African Rift region.

A range of instrumental approaches are utilized within the discipline of isotope geochemistry. Light elements such as H, O, C, and N are measured using gas source isotope ratio mass spectrometry. In this method, the material of interest is converted to a gas, ionized, and the relative abundance of the elements relative to a standard of known composition by using magnetic analyzer. Heavy elements such Ca, Sr, Cu, Pb, S, U, and Th are usually measured using thermal ionization mass spectrometry (TIMS) or multi-collector inductively coupled plasma mass spectrometry (MC-ICPMS). In TIMS analysis, samples are heated leading to ionization before being focused into beams by an electromagnet. The more recently developed technique of MC-ICPMS allows the measurement of a greater range of isotopes and has a significantly higher sample throughput compared to TIMS. Direct sampling methods such as laser ablation analysis and ion microprobe allow spatially resolved, minimally invasive, high-resolution sampling of a range of materials and has the added advantage of avoiding the need for chemical sample preparation facilitating high sample throughput.

In the future, isotope geochemistry is likely to be applied far more frequently in archaeology due to the greater availability of analytical instruments and the higher throughput of samples, made possible by MC-ICPMS and direct sampling. Additionally, isotope systems that have not been applied in archaeological research may yield interesting results in the future.

Introduction

The introduction of stable isotopes into archaeological research began in the 1970s and revolutionized the ways in which several key issues are studied, including early hominin diets, subsistence and spatial organization of forager societies, and individual life histories, among others (Makarewicz and Sealy 2015). Isotopic analysis of bones, teeth, and other organic tissues is a tool for the quantitative reconstruction of past human diets, providing an archaeological measure of subsistence that complements studies in zooarchaeology and archaeobotany.

Isotopic research is based on the premise that "you are what you eat," in other words, that the

isotopic composition of an organism's tissues is a function of the composition of its diet. Nevertheless, isotopic values do not have direct dietary meaning and need to be analyzed in an environmental context. The isotopic values for the vegetal and animal foods potentially available for forager populations in a given environment, known as the "isotopic ecology," provide the context for the interpretation of past foragers' diets.

Definition

The different chemical elements that constitute all organic tissues (e.g., carbon, nitrogen, oxygen) are defined by the number of protons in their nucleus, which varies among elements and is unique to each of them. For example, carbon has six protons, nitrogen seven, and oxygen eight. An isotope is a variety of a chemical element defined by the number of neutrons in its nucleus. For instance, carbon has three isotopes used in archaeology, ^{12}C, ^{13}C, and ^{14}C, possessing, respectively, six, seven, and eight neutrons in the nucleus (Fig. 1). These carbon isotopes have different atomic masses that condition whether isotopes are stable, like ^{12}C and ^{13}C, or radioactive, like ^{14}C. Stable isotopes do not change in abundance through time after an organism dies, whereas radioactive isotopes decay at a constant rate and are therefore useful as a radiometric dating tool.

Stable isotope values are a ratio between the heavier and the lighter isotope of each element ($^{13}C/^{12}C$, $^{15}N/^{14}N$). Since absolute abundances of these isotopes are very small, this ratio is standardized by comparison to international reference material (Vienna-Peedee Formation *Belemnitella americana* (V-PDB) for ^{13}C and atmospheric N_2 (AIR) for ^{15}N), producing δ values and then multiplied × 1000 (‰) as follows:

$$\delta(‰) = \left[\left(R_{sample}/R_{standard}\right) - 1\right] 1000$$

R is the ratio of the heavier to the lighter isotope.

Isotopic Fractionation

The process of incorporating and metabolizing nutrients involves chemical reactions in which nutrients are the dietary input or "substrate" of the reactions, an organism's tissue (e.g., bone) is the "product," and the excreta (urine, feces) are the output. Lighter isotopes of a given chemical element undergo reactions at faster rates than heavier isotopes, since bonds between the lighter isotopes are broken more easily than those between the heavy isotopes: for example, ^{12}C reacts faster than ^{13}C. In the case of animals, the

Isotopic Studies of Foragers' Diet: Environmental Archaeological Approaches, Fig. 1 Atoms of the three carbon isotopes used in archaeology

differences in reaction rates produce a concentration of molecules of the lighter isotopes in the excreta, resulting in impoverished $\delta^{13}C$ values, while the tissues that constitute a living organism are enriched in the heavier isotope. This effect is called "isotopic fractionation" and produces a systematic isotopic enrichment in every step along trophic chains. In the case of $\delta^{13}C$, fractionation is on the order of +1.5‰ and + 3‰ for $\delta^{15}N$, although there is interspecific variability (Schwarcz and Schoeninger 2011). Isotopic fractionation provides the basis for assessing paleodiets. Without it, all the organisms inhabiting a region would have the same isotopic abundances and thus provide no paleodietary information. This is actually the case with chemical elements with large atomic weight and small inter-isotope differences, characterized by negligible fractionation (e.g., $^{87}Sr/^{86}Sr$).

$\delta^{13}C$: A Marker of Photosynthetic Pathways

Photosynthesis allows plants to synthesize nutrients, including carbon, from sunlight and atmospheric carbon dioxide (CO_2). There are three alternative photosynthetic pathways (Ehleringer and Cerling 2001). The C_3 or Calvin-Benson pathway synthesizes CO_2 in the form of molecules with three-carbon atoms, with an average $\delta^{13}C$ value of −25‰, which ranges between −34‰ and −20‰. Diverse factors produce variation in these values, such as the existence of carbon reservoirs in closed forested environments, known as the "canopy effect." C_3 plants include most species from temperate and subarctic regions and high-altitude settings in general. The C_4 or Hatch-Slack pathway synthesizes atmospheric CO_2 as four-carbon molecules with an average $\delta^{13}C$ value of −12‰ and a range of −10‰ to −14‰. This pathway is characterized by a smaller isotopic fractionation and a more efficient use of nutrients, part of a physiological adaptation to arid and warm climates. C_4 species include maize, sugar cane, and tropical grasses. Finally, the crassulacean acid metabolism (CAM) pathway is characterized by the facultative capacity to alternate between the C_3 and C_4 mechanisms according to prevailing circumstances, producing an isotopic range that overlaps with that of both C_3 and C_4 plants. It includes a small number of taxa, such as succulents from desert environments.

Herbivores' $\delta^{13}C$ values are positively correlated with those of their diet, providing evidence of the plants consumed and, based upon this, paleoecological conditions. On the other hand, marine algae and plankton obtain their carbon from dissolved inorganic carbon, enriched by 7‰ with respect to atmospheric CO_2. Therefore, tissues of marine animals are enriched in comparison to those from terrestrial ecosystems.

$\delta^{13}C$ values can be obtained from two main components of bone: organic, or collagen, and inorganic, or apatite. Experimental work has demonstrated that the collagen isotopic signal reflects an average of the sources of protein consumed (e.g., meat), while the apatite signal reflects an average of the total diet (proteins, carbohydrates, and lipids). The integration of $\delta^{13}C$ values from collagen and apatite provides additional dietary information (Ambrose and Norr 1993).

$\delta^{15}N$: A Marker of Trophic Position

In terrestrial ecosystems, nitrogen is ultimately derived from soils. Soils from cool and moist areas, such as forests, tend to have low $\delta^{15}N$ values, whereas soils from warm and dry ecosystems, such as deserts, have high $\delta^{15}N$ values. These values are passed on to herbivores, plus ca. 3‰ due to isotopic fractionation. The stepwise increase in $\delta^{15}N$ values marks every step within a food web and thus provides important data on the trophic position of animals.

The $\delta^{15}N$ values of marine plants are about 4‰ higher than those of terrestrial ones. Additionally, marine food webs are usually longer than those from terrestrial ecosystems, providing more opportunities for isotopic fractionation and trophic enrichment. Globally, marine animals tend to have much higher values than terrestrial animals.

Foragers and Isotopic Studies

The definition of foraging societies is not free of ambiguity and discrepancy, given the inherent complexity of human organization of subsistence and divergent theoretical views. Nonetheless, it can be stated that foragers' subsistence relies to varying extents on gathering plants and hunting

Isotopic Studies of Foragers' Diet: Environmental Archaeological Approaches, Fig. 2 South American foragers: (**a**) Hoti family returning from a fishing and gathering trip (Venezuela); (**b**) Nukak man fishing with a bow and harpoon (Colombia). (Photographs courtesy of Gustavo G. Politis)

and fishing animals (Fig. 2). They do not control the reproductive cycle of the resources they consume to any great extent when compared to farming and herding societies. Generally, this is equivalent to the "hunter-gatherer" category (Kelly 2007; Politis 2007).

The combined use of $\delta^{15}N$ and $\delta^{13}C$ values provides a means to quantify the main food classes consumed by foragers in various local contexts around the world. Most importantly, it provides subsistence data on the scale of the individual, an analytical target that is usually hard to reach, providing access to issues such as subsistence variation by age and gender. In addition, subsistence can be studied at the population level as well. Stable isotopes have contributed to assessments of the dietary role of vegetal foods (C_3 or C_4), terrestrial animals occupying diverse trophic positions, marine animals including shellfish, fishes, and mammals, and freshwater resources. On this basis, it is possible to evaluate variation across time and space in behaviors along the foraging spectrum (Kelly 2007).

Historical Background

Vogel and van der Merwe (1977) conducted the first stable isotopes study in archaeology, presenting an assessment of carbon isotopes in collagen from human bones from the Woodland period in Eastern North America. Around the same time, DeNiro and Epstein (1978) presented an isotopic study of organisms fed controlled diets, lending definitive support to the assertion that the diet determines the isotopic composition of animal tissues. Tauber (1981) developed the first isotopic test case for the consumption of marine foods by foragers, focusing on the Danish Mesolithic and Greenland Eskimos. Following these pioneering studies, isotopic research began to gain wide acceptance and, since the end of the 1980s, has grown in scholarly scope, as well as in geographical extent. The series of *Advanced Seminars on Paleodiet* beginning in 1986 witnessed and encouraged much of the methodological and theoretical growth visible in the archaeological field today. Analysis of stable isotopes has become a routine worldwide.

Key Issues/Current Debates

Isotopic Ecology: Studying the Foragers' Menu

Isotope data from human remains must be interpreted in the context of the values of the potentially consumed foods, or the isotopic ecology. This is an integral part of the paleodietary study of forager societies, because the values of

human samples do not carry a precise dietary meaning per se. For example, a $\delta^{13}C_{collagen}$ value of −15‰ from a human sample indicates an enriched signal, which may suggest the consumption of a certain amount of protein from marine mammals, fluvial fishes, or some terrestrial herbivores, among other likely explanations. Interpretations must be adjusted by placing human values in the context of isotopic ecology. Usually, samples of archaeological origin are analyzed as well as modern samples, in order to widen the taxonomic range, in particular for plants. When modern samples are included as part of the context, it is fundamental to assess whether the organisms may have ingested foods that were not available in prehistoric times (e.g., agricultural forage, domestic animals). It is also necessary to correct the $\delta^{13}C$ values of modern samples for the so-called "Industrial" or Suess effect (ca. +1.5‰), which has altered global isotopic ratios by introducing carbon derived from fossil fuels, depleted in ^{13}C, to the atmosphere.

A first step for building an isotopic ecology is to define the foragers' potential menu on the basis of zooarchaeological and archaeobotanical evidences from the study area. This involves considering foods that might be unrecorded archaeologically, which is especially important for items with poor preservation potential (e.g., plant foods). Indeed, one of the merits of stable isotope research is that it permits inferences of past feeding behaviors that might otherwise be invisible.

The isotopic ecology must be local in terms of the archaeological problem at hand, since all vegetal and animal isotopic values vary with regional and local conditions – climate, nutrient availability, type of substrate, the existence of marine or terrestrial isotopic reservoirs, and physiological adaptations (Koch 2007). There is no "magic number" of samples providing a confident reconstruction of the isotopic ecology of a given region. The goal is to accurately characterize the isotopic variation of each of the main food resources available for foragers, since the use of inaccurate average and dispersion isotopic values for the foods eaten by humans will lead to wrong dietary interpretations. As a rule of thumb, the more complex the ecosystems where foragers make their living, the more extensive the isotopic ecology sampling should be.

A large-scale project directed by Andrzej W. Weber at the Lake Baikal region of Siberia, Russian Federation, provides an exemplary case of isotopic reconstruction of a complex ecological system intended to frame a regional study of forager populations inhabiting the area during the middle Holocene (Weber et al. 2011). Two main food webs are present in the region: (a) a *terrestrial food web* composed of C_3 plants consumed by herbivores (elk, red deer, hare), in turn consumed by carnivores (black bear, fox, dog), and (b) a *freshwater food web* of great complexity, as the Baikal is one of the largest freshwater ecosystems on Earth. The latter includes different groups of detrivorous and omnivorous fishes, fed on by seals (Fig. 3).

Plots (a) and (b) from Fig. 3 represent the terrestrial food web, and plots (c) and (d) depict the aquatic food webs from fluvial and lacustrine contexts. The $\delta^{15}N$ data show that most of the aquatic species are enriched with values above 10‰. On the other hand, most of the terrestrial species have $\delta^{15}N$ values below 10‰ with two exceptions: the herring gull, which includes fish in its diet, and the dog. As the authors suggest, "Since in most prehistoric societies, dogs are expected to feed mostly on human leftover food, dog stable isotope signatures are frequently accepted as a good measure of human diet at a group level…" (Weber et al. 2011: 542). The Baikal freshwater isotope ecology is extremely complex, in particular regarding $\delta^{13}C$ values. High variability in lake bathymetry, sunlight access, and availability of nutrients all produce a wide isotopic range (Fig. 3c) that stands in sharp contrast to the homogeneous C_3 terrestrial environment (Fig. 3a).

To summarize, the success of the Baikal isotope ecology project lies in having thoroughly characterized the isotopic ranges of the alternative food classes available for foragers from terrestrial and freshwater ecosystems. On this basis, the authors are able to discriminate two main types of diet, "Game-Fish" and "Game-Fish-Seal," each related to different ecosystems. This study

accentuates the need for archaeologists to determine the foraging menu via consideration of available food items; these provide the isotopic ecological context from which past forager diets can be reconstructed.

Isotopic Visibility of Feeding Behaviors: How Much Is Enough?

Isotopic results from human samples provide an *average* of the values of the foods consumed during a given period of time. Therefore, isotopes do not provide a record of rare feeding events. Beyond this, it is fair to ask how much of a given food must be eaten for it to be visible in the isotopic record. Currently, some of the main variables that determine the isotopic visibility of ancient feeding practices are known, while others remain unknown. The target of isotopic analyses is usually that of classes of foods grouped by similarities in their $\delta^{13}C$ and $\delta^{15}N$ isotopic ranges (e.g., C_3 or C_4 vegetal species, ungulates from open vs. forested environments, marine vs. terrestrial protein). This is a kind of taxon-free approach like that applied in paleontology, where the relevant variable is the niche that a species or population occupies. Correspondingly, the scale of analysis of isotopic

research does not usually reach the level of individual species, since different species occupying similar niches may present similar isotopic signals, as recorded for Baikal fish (Fig. 3d).

Figure 4 illustrates a simple dietary reconstruction with two isotope systems ($\delta^{13}C$ and $\delta^{15}N$ from collagen) where two classes of foods are present: proteins from marine and terrestrial mammals. It shows that three individuals consumed these two dietary sources in the following proportions: (A) 100% terrestrial protein, (B) 50% terrestrial and 50% marine protein, and (C) 100% marine protein. In a simple situation such as this, with only two classes of food or "isotopic end members" that are isotopically distinct, a linear mixing model can be used. Basically, the closer one sample falls to an end member, the larger the dietary importance of that end of the continuum (Schwarcz and Schoeninger 2011).

The $\delta^{13}C$ and $\delta^{15}N$ values of sample A represent consumed terrestrial protein, plus the isotopic fractionation affecting the relation between substrate and product (diet and bone collagen in this case). The same occurs with sample C, which points to a 100% marine-based diet. Finally, sample B falls halfway along the theoretical mixing line, as might be expected for a diet combining both sources of protein in equal proportions. If isotopic variation of the terrestrial and marine isotopic end members were small and the spacing between them large, as in Fig. 4, a relatively small proportion of either type of protein in the total diet (e.g., 15%) would be isotopically visible. As isotopic variation of the end members increases, the spacing between them decreases, and larger inputs of the minor protein source are necessary in order to be visible. Therefore, the answer to "How much is enough?" depends on the local isotope ecology, which provides the average and dispersion values for the isotopic end members.

Isotopic Studies of Foragers' Diet: Environmental Archaeological Approaches, Fig. 4 Dietary reconstruction based on a "Linear Mixing Model" with two end members: terrestrial and marine protein

In real cases, usually there are more than two dietary sources present, increasing the complexity of the isotopic ecology and therefore of the study of forager paleodiets. The use of several isotopic tracers from organic and inorganic bone phases increases resolution. Recently, dietary mixing models have added powerful analytical tools to reconstruct foragers' subsistence.

Forager Diet, Mobility, and Settlement

In forager societies, subsistence is tied to mobility and geographical organization (Kelly 2007; Politis 2007). In this context, isotopically based dietary studies may offer spatial insights, in particular in cases that involved the consumption of foods with a spatially circumscribed availability and a distinct isotopic signature. This is the case with marine mammals and fishes, usually enriched in both $\delta^{13}C$ and $\delta^{15}N$ (Schwarcz and Schoeninger 2011). In some regions, this is also the case for fluvial or lake-dwelling mammals and fishes, enriched in $\delta^{15}N$ and usually depleted in $\delta^{13}C$, as shown in Baikal seals (Fig. 3d; Weber et al. 2011).

In a classic article, Sealy and van der Merwe (1986) tested a hypothesis that suggested a seasonal round between the coast and the hinterland for forager societies inhabiting the Cape of South Africa during the Late Holocene. This "seasonal model" of spatial organization – inspired by historic records – would produce a homogeneous isotopic signature mixing marine and terrestrial foods. Isotopic analyses of human samples from both ends of this alleged seasonal round showed at

least two different types of diet: people from coastal sites with marine-based diets and inland people who consumed negligible amounts of marine resources. This not only contradicted the expectations derived from the seasonal model but also suggested the existence of restricted ranges of mobility for foragers consuming marine foods. Similar patterns of isotopic coastal-inland differentiation have been recorded for regions of Australia, Peru, Argentinean Patagonia, and the Northwest Coast of North America. These cases highlight the attraction of productive coastal settings to foraging societies, leading to spatially restricted home ranges and high demographic densities. On the other hand, wide territories integrating the coast and the hinterland have been suggested for Mesolithic Denmark, among other cases. This information is well suited for the analysis of catchment areas via the application of patch choice models derived from foraging theory.

These and other case studies help place dietary information into a geographic context. Isotopic reconstructions of forager diets are currently being developed to integrate diverse aspects of cultural geography such as territorial organization, foraging ranges, and logistical spheres of mobility. This is enhanced by the use of other isotope systems described below.

Future Directions

Forager Geography and Life Histories: Strontium and Oxygen Isotopes

Following the lead of research on complex societies such as the Maya and Tiwanaku, studies of forager subsistence are progressively including isotopic markers of geographic residence (Bentley 2006; Price and Burton 2011). Strontium ($^{87}Sr/^{86}Sr$) and oxygen isotopes ($^{18}O/^{16}O$) are at the forefront of this methodological advance.

Stable isotope analyses can be performed on different organic tissues: bone, teeth, and soft tissues such as hair and nails. Bones are remodeled throughout life, whereas teeth, hair, and nails have incremental growth patterns and do not remodel once formed. The isotopic signal retrieved from each tissue reflects an average of the diet during the period of its formation. In the case of bones, the remodeling process is on the order of a decade and is active until the death of the individual, offering an isotopic signal that averages the diet during the last years of life. Teeth, on the other hand, form only during the first years of life, providing an evidence of diet during different stages of childhood. Hair and nails form rapidly and incrementally, providing dietary information on very brief periods of life, offering monthly dietary resolution (Schwarcz and Schoeninger 2011).

Strontium isotopes ($^{87}Sr/^{86}Sr$) have large atomic masses and differ little from each other. Therefore, rates of chemical reaction are very similar, and isotopic fractionation between substrate and product is negligible. In this case, all of the organisms in a given region present the same isotopic abundances determined by the chemical signatures in the local geology, which are passed on to soils, circulating water, plants, animals, and humans (Bentley 2006).

The use of $^{18}O/^{16}O$ ratios as markers of place of origin is based on two central facts: (a) Isotopic ratios in meteoric precipitations vary geographically according to altitude, humidity, temperature, and distance from the ocean; (b) isotopic ratios in human tissues depend on the water imbibed and, to a lesser extent, oxygen in air and food sources. Thus, oxygen values from human remains contain an averaged record of the places where a person lived during the period of time represented in the sampled tissue.

These isotope systems must be used in the context of different frames of reference: biologically available strontium in the case of $^{87}Sr/^{86}Sr$ and isotope values in water sources in the case of $\delta^{18}O$. The natural variation in isotopic abundances between different regions will determine the resolution that can be achieved in archaeological reconstructions (i.e., which regions have an isotopically distinct signature). Since these isotope systems are independent from each other and may offer complementary insights, their combined use is the best strategy.

Recent studies by Eerkens et al. (2014, 2016) for Central California illustrate the strength of this

approach to evaluate mobility and residence patterns in foragers. The authors analyzed isotope values in serial samples of third molars encompassing between 9 and 20 years of age, suggesting that in many cases there is large variability in the consumption of resources within short spans. This can be related to changes of residence, seasonality of resources, exchange, and scarcity periods, among others. In addition, by comparing different tissues they conclude that several individuals migrated at different stages of their lives and that an individual can be both "local" and "nonlocal" at different during along life. By revealing intra- and interindividual dietary and geographic differences, we have the capacity to assess forager social organization, subsistence, interpersonal violence, and life history traits (see next).

Dietary Mixing Models

Mixing models have recently been developed to convert a consumer isotopic values into quantitative estimates of the contribution of different resources, such as IsoSource, SIAR, and FRUITS (Phillips et al. 2014). These models have evolved by incorporating the uncertainties associated with the main sources of variability – isotopic enrichment, consumer, and sources – and considering a greater number of potential resources with different elementary concentrations. In the context of hunter-gatherer studies, dietary mixing models are just beginning to be applied (Newsome et al. 2004; Tsutaya et al. 2016). In a pioneering work, Newsome et al. (2004) implemented IsoSource to study the hunter-gatherer diet of the California coast during the early and middle Holocene, recording a decline in the importance of marine resources in the late period, particularly marine fish, accompanied by an increase in terrestrial resources.

In recent years, new mixing models have been developed utilizing a Bayesian statistical framework (Phillips et al. 2014), allowing incorporating prior information on the relative importance of different food classes and estimating the dietary contributions of a resource probabilistically. One of these models, within the framework of a Bayesian environment, is the Weaning Age Reconstruction with Nitrogen isotope analysis (WARN) of particular interest for studies of forager life history. Its purpose is to establish the ages of beginning and end of weaning in human populations (Tsutaya and Yoneda 2013). Breastfeeding and weaning are processes that involve a change in diet in the lives of individuals, being therefore recorded in isotope values. These processes are closely linked to the fertility, growth, mortality, and morbidity in forager populations. In a recent paper, Tsutaya et al. (2016) evaluated the role of ceramic technology and plant availability in the breastfeeding and weaning practices of a hunter-gatherer population of the late Jomon period in eastern Japan. Using WARN, these authors compared the timing for weaning in different populations of foragers (Fig. 5, Tsutaya et al. 2016). The authors observe large variation worldwide with foragers completing weaning between 1 and 4 years of age. This is a promising framework for the comparative analysis of key socio-ecological processes.

Overcoming Analytical Limitations: Compound–Specific Isotope Analyses

Isotopic analysis at the level of specific compounds of bone, including amino acids, fatty acids, and cholesterol, is a new technique that allows a high-resolution alternative to bulk tissue analysis of $\delta^{13}C$ and $\delta^{15}N$ (Evershed et al. 2007). Compound-specific studies provide a means to assess the dietary contribution of particular food classes, overcoming some limitations of forager paleodietary reconstruction, such as the $\delta^{13}C$ overlap of C_4 plants and marine resources and the ^{15}N enrichment prevalent in arid environments. Bone cholesterol in particular has been shown to reflect the whole diet, playing an analogous role to apatite and contributing to assess its preservation.

Since their introduction in archaeology 40 years ago, stable isotope analysis has provided a tool for the quantitative reconstruction of forager subsistence, thereby enlarging the range of topics addressed. Currently, the isotopic field has grown to include studies of isotopic ecology in complex ecosystems, forager diet, and geographical issues including foraging ranges, territories,

and migrations, with a potential resolution reaching the scale of individual life histories. The theoretical and methodological limits of the isotopic revolution in archaeology lie still far ahead.

Isotopic Studies of Husbandry Practices

Marie Balasse
CNRS/MNHN, Paris, France

Introduction

Assessment of husbandry practices in ancient times has long been made from analogy with (sub) contemporary traditional herding systems. Although these are still extremely useful for encompassing the range of possibilities, analogy may today be replaced by direct evidence.

Probably from the early steps of domestication processes in the Near East, in the early Pre-Pottery Neolithic, and certainly from the time when the first domesticates were diffused and acclimatized outside of the area of domestication, pastoral communities have developed husbandry strategies involving great zootechnical skills to insure the survival of their stock and enhance the exploitation of subsistence products. In prehistoric times, with the exception of rare and sometimes ambiguous iconographical sources, the only direct evidence of husbandry practices is constituted by animal skeletal remains. In particular, valuable information may be retrieved from the isotopic composition of the elements that make up bones and teeth. In historical periods, many written and iconographical accounts may inform on herding practices. However, because such sources may not always reflect the actual management of husbandry and spatial variability on a local scale, direct investigation from bone remains is also commonly conducted on assemblages from antiquity and medieval times.

Definition

Husbandry practices are essentially related to animal diet and breeding. Management of domestic animals' diet may start from their very young age with control of weaning, and includes a range of possibilities, depending notably on the scale of the husbandry: from the choice and management of pasture areas, including seasonal to interannual mobility between pastures, to the supply with forage in periods of food shortage. In mixed farming systems, the fodder may be a by-product or a product of cultivated crops. Management of animal reproduction includes the choice of mates and control of the mating period and duration of lactation.

Most of these zootechnical parameters may be approached by isotopic studies of bone and teeth. Among elements, the most commonly targeted for this purpose are carbon (δ^{13}C), nitrogen (δ^{15}N), oxygen (δ^{18}O), and strontium (^{87}Sr/^{86}Sr), whose

isotopic compositions are primarily related to – and therefore inform on – environment (climate, geology, soil history, vegetation cover) and plant and animal physiology. The list may be enlarged in the future with other major or trace elements currently under consideration for possible applications in this field. Most of the time, these elements are extracted from bone and tooth collagen and bioapatite, less commonly from individual bone collagenous amino acids and fatty acids (Copley et al. 2004).

Under high and middle latitudes, husbandry and related tasks are strongly punctuated by the seasonal cycle, driving both availability of plant and water resources and animals' biological cycle. For this reason, an important place is henceforth given to reconstitutions of animals' isotopic history at the infra-annual scale. This is made possible by studies involving serial sampling in teeth. Still, studies involving bulk analysis of bone and teeth remain very informative in many instances.

Key Issues/Current Debates/Future Directions/Examples

Animal Diet

Proximity of the Herd to the Settlement: The Example of Pig Husbandry

Management of animal diet has consequences for the degree of commitment and organization of labor within pastoral communities and may indirectly inform on the scale of husbandry. The closeness of the flock to the settlement, as opposed to extensive husbandry, may be assessed through the position of domestic animals in the anthropic ecosystem, with trophic chains possibly including by-products from animal exploitation and/or land cultivation. This point is particularly relevant for pig husbandry. Domestic pig is characterized by a great plasticity in terms of feeding behavior. When herded extensively in woodland, domestic pigs would have a diet similar to that of their wild counterparts, mainly herbivorous. Proximity of pigs to the settlement and human activities may result in its scavenging on consumption refuses, including animal products, which would raise it to an omnivore to carnivore level in the trophic chain. The relative position of the pig in the trophic chain may be inferred from the analysis of bone collagen $\delta^{15}N$. The principle used is the stepwise enrichment in ^{15}N along the trophic chain. Crucially, given that $\delta^{15}N$ of plants, at the first level of the trophic chain, are primarily defined by local soil parameters (and physiology), pig $\delta^{15}N$ values rarely speak by themselves. They must be compared to $\delta^{15}N$ values measured in other animals of the same ecosystems, including unambiguous representatives of herbivores and carnivores (Ervynck et al. 2007).

Integrating Agricultural Resources into Animal Diet

In mixed farming systems, the interweaving of animal husbandry with plant cultivation may sometimes be detected from the analysis of bone collagen $\delta^{13}C$. This applies especially when the cultivated crop is a C_4 plant in a wild environment heavily dominated by C_3 plants, the difference in $\delta^{13}C$ between these two photosynthetic pathways being inherited by the consumers. This is the case, for example, in China, where millet, a C_4 cereal, was cultivated from the Early Neolithic. At Xipo, a Middle Neolithic site in the Yellow River basin, a substantial contribution of C_4 plants, most probably millet, was shown in the diet of domestic pigs, emphasizing the interdependence of husbandry and agriculture in these societies (Fig. 1a). A system where agricultural products are redistributed between animals and humans depending on fluctuations in agricultural yields and wild resources was described as a key to the stability of the subsistence strategy (Pechenkina et al. 2005). Another domestic crop representative of the C_4 photosynthetic pathway is maize. Its contribution to camelid pastoralism was demonstrated in the first millennium CE at the site of Conchopata in the Peruvian highlands (Finucane et al. 2006). From their bone collagen $\delta^{13}C$ values, camelids at the site could be separated into two groups (Fig. 1b) possibly corresponding to two different species: one group of camelids (llamas?) kept by the settlement and supplied with maize fodder and one group (alpacas?) fed pure C_3 diet, kept on highlands grasslands.

(Data from Pechenkina et al. 2005); (**b**) introduction of maize in the diet of domestic camelids in Middle Horizon culture in Peru. (Data from Finucane et al. 2006)

Exploitation of Estuarine and Marine Resources

Coastal and marine ecosystems are characterized by isotopic values different than those measured in continental areas. This specificity was sometimes used to highlight the exploitation of estuarine and marine resources by herders for their stock. The exploitation of estuarine salt marshes to graze cattle and caprines is still a common practice in Northwestern Europe and is widely described by historical accounts from medieval times. In England, the antiquity of this practice was confirmed by an isotopic study using the principle that salt-marsh plants have significantly higher $\delta^{15}N$ ratios than other terrestrial plants. Comparing bone collagen $\delta^{15}N$ values of cattle and caprines from Bronze Age sites in the Southwestern coast of England, Britton et al. (2008) were able to show that they were significantly

higher than those measured in inland sites, reaffirming the hypothesis of salt-marshes exploitation previously suggested by other archaeological evidence, including cattle and sheep/goat footprints tracks and the presence of halophytic plant remains in herbivore coprolites found at the sites.

The use of marine resources – including fish, shells, and seaweed – to feed domestic cattle, caprines, horse, and pig is also a widespread practice, which can be detected through stable isotope analysis. Plants and animals from marine ecosystems tend to have higher $\delta^{13}C$ values than those measured in terrestrial C_3 plants-dominated ecosystems. Additionally, because food chains are extended in marine ecosystems, most marine animal resources have higher $\delta^{15}N$ values than those encountered in terrestrial animals. The introduction of marine fish in the diet of domestic animals can therefore be detected by a concomitant raise in bone collagen $\delta^{13}C$ and $\delta^{15}N$ values compared to what would be expected for a terrestrial diet. Guiry et al. (2012) conducted isotopic analyses on pig remains from seventeenth century fishing stations in Newfoundland and were able to highlight the presence of two clearly distinct groups of pigs with spectacular differences in both $\delta^{13}C$ and $\delta^{15}N$ values. The pigs with higher $\delta^{13}C$ and $\delta^{15}N$ values were most probably those raised locally with great access to marine-derived food, in contrast to their European counterparts raised on terrestrial diet.

The feeding on marine seaweed may in the same manner be reflected by $\delta^{13}C$ values higher than those measured in animals grazing on terrestrial C_3 pastures. The use of marine seaweed as fodder for cattle, sheep, and horse is a common practice in the Northwestern Atlantic area, attested from historical sources from Early Middle Ages on. In humid insular contexts, particularly, where terrestrial pastures are reduced in the winter while climatic conditions prevent the constitution of dry fodder, seaweed may be a valuable resource to complement the flocks over the bad season. Because this practice is often restricted seasonally, the greatest opportunity to detect it is by performing sequential sampling in tooth enamel. Concomitant analysis of enamel bioapatite $\delta^{13}C$ values, reflecting diet, and $\delta^{18}O$ values, reflecting climate, permits to access seasonal changes in diet and to highlight a potential contribution of seaweed resources in the winter (Fig. 2c). This principle was used to demonstrate a recurrent significant contribution of seaweed to the diet of sheep in the Neolithic site of Holm of Papa Westray (third millennium BCE) in the Orkney archipelago. The contribution occurred in the winter and in the form of fresh seaweed, so it could not be said whether sheep were intentionally fed this resource by the herders or if this resulted from the gathering by the animals of a fully accessible resource washed ashore by storms (Balasse et al. 2006).

Leaf Foddering

Compensating for restricted availability of grass during dry summers or snowy winters and/or over periods of stalling sometimes involves the use of tree leaves. The practice was widespread in Europe until recent history from Norway to the Mediterranean area. It is directly evidenced at middle Neolithic sites, where botanical remains including twigs and leaves have been retrieved in cattle and small stock dung deposits. Unfortunately, the retrieving of dung layers with good preservation of botanical remains is exceptional in archaeological contexts. Alternatively, the practice of leaf foddering can be investigated through the analysis of $\delta^{13}C$. Plants grown in closed forests are marked by the canopy effect resulting in a lowering of $\delta^{13}C$ values. Those are passed onto animals feeding on them (Fig. 2b). At the Middle Neolithic site of Bercy, France (fourth millennium BCE), previous archaeobotanical studies demonstrated the presence of a dense oak tree forest on the alluvial terraces nearby the site, exploited for firewood and partly cleared for agricultural purposes. Seasonal feeding on plants marked by the canopy effect was suggested by low $\delta^{13}C$ values in sheep and cattle tooth enamel, suggesting that the forest was also exploited for winter leaf foddering (Balasse et al. 2012).

Herd Mobility and Trade

In extensive pastoralism, the search for good quality pastures all year round involves compensating

Isotopic Studies of Husbandry Practices, Fig. 2 Detection of seasonal changes in diet, through sequential sampling (here on a sheep second lower molar) and sequential analysis of stable carbon ($\delta^{13}C$, *black symbols*) and oxygen isotope compositions ($\delta^{18}O$, *open symbols*) of tooth enamel. (**a**) Expected values for a sheep grazing in terrestrial pastures. (Data from Balasse et al. 2006); (**b**) evidence for winter leaf foddering. (Data from Balasse et al. 2012); (**c**) evidence for winter seaweed consumption. (Data from Balasse et al. 2006)

for seasonal fluctuation in resource availability through altitudinal or longitudinal mobility. Altitudinal mobility sometimes implies a change in vegetation types and plant species available for graze. Particularly in subtropical regions, due to an altitudinal gradient in the relative proportion of C_3 and C_4 plants, with C_4 grasses dominating in low-altitude grasslands and C_3 grasses becoming more abundant to dominant in highlands pastures, altitudinal mobility may be reflected in $\delta^{13}C$ values mimicking changing proportions of C_3/C_4 plants in the diet throughout the year. However, when assessing mobility from changing proportions of C_3/C_4 plants in diet, one might also have to deal with two potentially interfering factors: plant selectivity by herbivores – especially as far as cattle are concerned – and seasonal changes in the proportion of C_3/C_4 plants at the local scale (Balasse et al. 2002; Balasse and Ambrose 2005).

Longitudinal mobility can be addressed through strontium isotopic analysis, the most commonly used tool to assess mobility and migration in the past (Bentley 2006). Sr isotopic signatures are mostly inherited from eroding geology through soils and waters into the food chain. The Sr isotopic signature from the geological material depends on the nature and age of bedrock and therefore varies on geographical scales with local parameters. In coastal areas, the local Sr isotope signature may be considerably influenced by the marine signal through sea spray. Other factors including a dust component may be taken into account. Mobility between areas with different geology and/or soil history and between coastal and inland areas may be reflected in changes in Sr isotope ratios. This principle has occasionally been applied to domestic animal assemblages with the aim of investigating mobility at the seasonal scale or mobility during the lifetime, potentially related to trade (Balasse et al. 2002; Bentley and Knipper 2005; Viner et al. 2010; Sjögren and Price 2012). The most

difficult prerequisite of this method is to evaluate accurately the range of variation of the local Sr isotope signature. It is recommended to define the local archaeological signature from archaeological teeth of animals with a restricted range of habitats (Bentley 2006).

Animal Reproduction: Seasonality and Season of Birth, Weaning, and Duration of Lactation

Domestication has lead to the attenuation or suppression of some of the physiological expressions of seasonality, including seasonality of the breeding cycle. However, the reproductive patterns of domesticated small ruminants are still strongly driven by the photoperiodic cycle, while the breeding cycle of other domesticates like cattle and pigs, when raised extensively, tends to be synchronized with the vegetation development cycle. The herder may directly influence this reproduction pattern, essentially through management of diet and mating, in order to extend or conversely to reduce the breeding period. Birth management strategies are mainly influenced by herd size, residential mobility, and, in more recent times, market timetable (Balasse et al. 2003). For all these reasons, although it is most likely that breeding in prehistoric herds was seasonally restricted, the duration of birth period and distribution of birth over this period (with a possible bimodality) need to be inferred from the archaeological record.

Assessment of birth distribution may be performed through the analysis of tooth enamel $\delta^{18}O$. The $\delta^{18}O$ value of tooth enamel is related to that of ingested water, mainly reflecting local surface water and precipitation. Seasonal variations in precipitation $\delta^{18}O$ are recorded in enamel during tooth mineralization and can be reconstructed through sequential analysis along the axis of tooth growth. Seasonality of birth may be investigated through a study of interindividual variability in the sequence of the seasonal cycle tracked in a given tooth. The assessment is performed by a comparison of the position in the tooth crown where the lowest and/or highest $\delta^{18}O$ values are measured (Fig. 3). This principle was applied, for example, on the Late Stone Age site of Kasteelberg in Southwestern Cape (South Africa), where it was used to highlight two lambing seasons for sheep, in agreement with descriptions by European observers of the Khoekhoe husbandry systems at the beginning of the eighteenth century. This result suggested either females lambing more than once a year or subdivision of the flock and births scheduled at different times of the year. Several implications could be drawn on the role of sheep in the subsistence economy, residential mobility strategy, and the use of sheep mortality profiles for interpretation of season of occupation of the site. Similar analytical protocols were developed in order to investigate birth seasonality in cattle (Towers et al. 2011; Balasse et al. 2012) and pig (Frémondeau et al. 2012).

The season of birth cannot be inferred from the pattern of intra-tooth variation in $\delta^{18}O$ values alone until the time resolution of the isotope signal in enamel bioapatite, influenced by the duration of enamel mineralization, is clearly established. Comparison of results must be made with modern reference sets (Fig. 3c, d).

In contexts where milk exploitation is attested, because lactation is initiated with the offspring's birth, seasonality of birth and duration of lactation influence directly the seasonal availability of milk. Duration of lactation may be approached indirectly through weaning age. The change of diet occurring during the weaning process is also a step down the trophic chain: the young mammal stops feeding on milk, a product elaborated by its mother. This change is recorded in tooth dentine. The $\delta^{15}N$ of dentine collagen reflects the trophic level at time of tooth formation. It is possible, by performing sequential sampling of dentine along the tooth, to observe the decrease in $\delta^{15}N$ of collagen at weaning time. Results from a study conducted on cattle teeth from the Middle Neolithic site of Bercy (France) suggested early weaning, possibly reflecting a shorter lactation for Neolithic cows, compared to modern improved breeds. This kind of result is a step toward a better estimation of the capacity of prehistoric dairy husbandry, which may help in the

Isotopic Studies of Husbandry Practices, Fig. 3 Investigation of seasonality and season of birth in past herds, through analysis of tooth enamel stable oxygen isotope ratios ($\delta^{18}O$). (**a**) Birth spacing is reflected in interindividual variability in the position of the highest $\delta^{18}O$ values in the tooth crown (*ERJ* enamel-root junction). This variability may also reflect differences in tooth size and timing of growth. (**b**) Modeling of data permits estimation of the period of the cycle (1 year record) and normalization of the distance by this period, in order to eliminate the tooth size effect. (**c**) Normalized data is used to infer birth spacing (or birth seasonality). (**d**) Estimation of the season of birth implies comparison with modern reference sets obtained on animals with known birth season. (Data from Balasse et al. 2012)

future to evaluate the role of milk in subsistence economies (Balasse and Tresset 2002).

Future Directions

Isotopic studies of husbandry practices have naturally focused on the analysis of animal skeletons. Analysis of botanical remains might also prove very relevant to the subject. Recent stable isotope studies of charred remains of domestic crops have shown how the practice of manuring could be highlighted through the analysis of $\delta^{15}N$, opening a new window on the interweaving of animal husbandry and crop cultivation in mixed farming systems which may have existed from the Early Neolithic in Europe (Bogaard et al. 2007; Fraser et al. 2011).

Israel: Museums

Caroline Tully
School of Historical and Philosophical Studies, University of Melbourne, Parkville, VIC, Australia

Introduction

With over 230 museums, the State of Israel has the most museums per capita in the world. These range in size and sophistication from small house museums to those representing state-of-the-art contemporary museum design, such as the Yad Vashem Holocaust History Museum. Israel's diverse assortment of museums covers time periods spanning prehistory to the present day. Not all museums are concerned with archaeology, and many focus on topics as varied as clandestine immigration, computers, folklore, founding figures, grain, military history, sport, transport, and visual art.

Definition

Museums that contain archaeological exhibits are of four main types. Small museums found in *kibbutzim* mainly focus on aspects of local history and can include geological, botanical, and zoological exhibits along with archaeological material. Regional museums such as the Hula Valley Regional Museum in the Upper Galilee can be more comprehensive, specializing in a particular subject such as prehistoric settlement. Site museums are connected to outdoor archaeological sites such as Masada or urban excavations such as the Burnt House or the Davidson Excavation and Virtual Reconstruction Center in Jerusalem. Large public museums such as the Eretz Israel Museum in Tel Aviv often incorporate art and ethnographic displays along with archaeological material. It is the latter type of museum, housing prominent archaeological collections, which will be covered here in chronological order according to their date of establishment.

Key Issues/Current Debates/Future Directions/Examples

Archaeology plays a significant role in the foundation narrative of the State of Israel, linking contemporary Israelis to both the ancient Israelites and the Jewish nation in ancient Palestine (Petrovato 2006). Archaeological excavation of biblical sites has been described as a "veritable form of prayer" (Ben-Yehuda 2007), and archaeological collections within museums, particularly objects dating to the First and Second Temple periods – the Iron Age, Persian, Hellenistic, and Early Roman periods, considered the era of the original Jewish community in Israel – assume a religious aura when appearing to substantiate the biblical account. This functions, to an extent, to legitimize the repatriation of the Jewish diasporic community to its biblical homeland, encourages public support for the Israeli nationalist enterprise, and renders Palestinian (often referred to by the more generic term "Arab") culture less visible (Petrovato 2006). The museums of Israel are more than simply sites of nationalistic narrative, however, as they contain a vast range of artifacts of immense importance to the history of the Levant as well as the wider Eastern Mediterranean and beyond.

Rockefeller Museum, Jerusalem

Originally known as the Palestine Archaeological Museum, the Rockefeller Museum in East Jerusalem was established with the aid of a donation by

American philanthropist, John D. Rockefeller, Jr., on the initiative of archaeologist and director of the Oriental Institute in Chicago, Henry Breasted. Designed by British architect, Austen St. Barbe Harrison, in a style incorporating elements from Eastern and Western architecture, with sculpted reliefs by British artist Eric Gill and decorative tiles by the Armenian artist, David Ohanessian, the museum opened in 1938. The Rockefeller Museum was the first building constructed specifically as a national museum in Palestine in which material from excavations would be exhibited locally, rather than being exported to foreign museums. The museum houses a collection of antiquities from excavations conducted in Palestine during the period of the British mandate (1919–1948) (Ibrahim 2006). John Henry Iliffe, British archaeologist and first keeper of the museum, initially planned to include an ethnographic exhibit displaying local Palestinian culture but was overruled by Breasted and Rockefeller. In line with Rockefeller's original stipulation, the museum consequently focused solely upon archaeology, excluding historical, biological, and ethnographic exhibits (Baruch and Kudish-Vashdi n.d.). Arranged in chronological order, the exhibit displays material ranging in date from the prehistoric era to the beginning of the eighteenth century CE. The two main galleries contain finds from major excavations in Palestine conducted in the early twentieth century, while several smaller exhibition rooms are organized thematically, containing Egyptian material, decorative features and statuary from Hisham's Palace near Jericho, carved wooden elements from both the Al-Aqsa Mosque and the Church of the Holy Sepulchre, coins, jewelry, and examples from Talmudic period Jewish culture. Outdoors, within the arcades surrounding the pool, architectural elements, sculptures, and stone sarcophagi are displayed.

Eretz Israel Museum, Tel Aviv

Founded in 1958 as the Haaretz Museum, the Eretz Israel Museum is situated in northern Tel Aviv, next to the Philistine archaeological site of Tel Qasile. Organized in a series of pavilions spread over the site, the museum was initiated by Tel Aviv resident, Dr. Walter Moses, who bequeathed his archaeological collection and library to the Tel Aviv municipality with the proviso that it builds a museum in which to house it. Beginning with the inauguration of the glass pavilion in 1959, which houses vessels dating to between 1500 BCE and 1500 CE, subsequent pavilions would be built over the years. The Numismatic Pavilion was inaugurated in 1962 and chronicles the history of coinage and monetary systems. This was followed in 1963 by the Ethnography and Folklore Pavilion, focusing on the Jewish ritual year. The Ceramics Pavilion, installed in 1966, features ceramic objects dating to between the Chalcolithic and Classical periods from Israel, Cyprus, Egypt, and Greece, as well as material from Africa and Central America. In addition, the pavilion houses objects from Tel Qasile, one of the first archaeological sites excavated within the new State of Israel, as well as the important cult furnishings from the Yavneh favissa excavated in 2002. The Man and his Work Center, displaying objects related to agriculture, crafts, domestic work, and rustic decorative arts, was established in 1982. This was followed by the Nechushtan Pavilion in 1983, devoted to metalwork and containing material from the excavations at the copper mining site of Timna in the southern Negev, including the components of an Egyptian-Midianite temple. The Alexander Pavilion of Postal History and Philately, founded in 1998, focuses on the evolution of the mail service from the mid-nineteenth century CE to the establishment of the State of Israel in 1948. Finally, the Rothschild Center, inaugurated in 2006, documents the activities of Baron Edmond Benjamin James de Rothschild who was instrumental in financially supporting the development of Jewish settlements in Palestine between 1882 and 1934. The museum also includes a complex housing olive presses, one of which dates to the Iron Age II, while outdoor sites such as Mosaic Square display mosaics from a Samaritan prayer house discovered on site, as well as others from Beit Guvrin and Tiberius. In addition, the museum incorporates the excavated remains of Tel Qasile, dating to the twelfth century BCE, which include

the remains of temples and a street lined by workshops, storerooms, and houses.

Israel Museum, Jerusalem

Situated on the famous Museum Row in Givat Ram near the Knesset (Israeli parliament) buildings, the Israel Museum was founded in 1965 as a collection dedicated to archaeology, fine art, and Jewish art and life. It was initially established with the help of American funds from publishing sales of Cold War propaganda in Israel and a land grant from the Israel government. The Israel Museum is a nonprofit company whose shareholders consist of the Ministry of Education, the Hebrew University, the Municipality of Jerusalem, the Bezalel School of Art, the Friends of the Bezalel Museum, and the Jewish Agency (Weyl 1995). The archaeology wing of the museum was established in 1965 by the children of Canadian businessman and philanthropist, Samuel Bronfman, to commemorate his 70th birthday and was renewed in 2010 as part of the refurbishment and expansion of the entire museum (Snyder 2010). Displaying material mainly discovered within Israel, the museum's permanent collection of archaeology contains 6000 artifacts, spanning the periods from prehistory to the Ottoman period. The collection primarily consists of provenanced material deriving from controlled archaeological excavations, on loan from the Israel Antiquities Authority. A smaller proportion derives from donations by private collectors (Dayagi-Mendels 2010) as well as material confiscated from dealers and looters (Blum 2002). The museum is not without its share of controversy. In 1986 the museum bought the collection of military leader, politician, and notorious looter, Moshe Dayan, for US$1,000,000, incurring protests and criticism from the Israeli archaeological community as such objects technically did not belong to a private individual to sell (Kletter 2003). In 1988 the museum paid $550,000 for an ivory pomegranate thought, on the basis of its inscription, to come from the Solomon's Temple in Jerusalem but which was later discovered to be a Bronze Age object with a fake inscription (Watzman 2005).

The archaeological collection of the Israel Museum is displayed in seven separate galleries organized chronologically. The "Dawn of Civilisation" incorporates the Early Stone Age/Lower Paleolithic period, "The Land of Canaan" focuses on the Early Bronze Age, and "Israel and the Bible" features material ranging from the Early Iron Age, the Late Iron/First Temple/Destruction and Exile period, to the time of Persian rule. "Greeks, Romans and Jews" is devoted to the Hellenistic period, including Herod's reign and the Early Roman/Second Temple period and Revolt and Destruction, and "Under Roman Rule" covers the Late Roman period. "The Holy Land" includes the Byzantine period, and "Muslims and Crusaders" covers the Medieval and Late Islamic periods up to the end of Ottoman rule of Palestine in 1917. The museum also features galleries devoted to neighboring cultures such as Anatolia, Cyprus, Greece, Egypt, Italy, Lebanon, Mesopotamia, Persia, Southern Arabia, and Syria. Other galleries focus on the Islamic Near East, glass, coins, and early Hebrew writing (Dayagi-Mendels 2010). The grounds of the Israel Museum also incorporate the Shrine of the Book, a highly symbolic building housing the *Dead Sea Scrolls*, material from the Essene community at Khirbet Qumran, and other rare and unique biblical manuscripts such as the Aleppo Codex. Funded by the Gottesman family of New York and designed by architects Armand Bartos and Frederick Kiesler, the structure evokes the shape of the jars in which the scrolls were found, while a black basalt wall contrasts with the white dome of the shrine symbolizing the scroll of the *War of the Sons of Light Against the Sons of Darkness* (Weyl 1995).

Hecht Museum, Haifa

The Hecht Museum, situated at the University of Haifa, was established in 1984 and is based around the private archaeological collection of wealthy industrialist, Reuben Hecht, founder of the Dagon Silos and member of the University of Haifa's Board of Governors. A new wing of the museum, inaugurated in 1998, consists of artifacts donated by the Hecht family, objects on loan from the Israel Antiquities Authority, and material from archaeological excavations conducted by the University of Haifa. The museum's permanent

archaeological collection is designed to showcase material from the Israelite period and is divided into two sections: one laid out in chronological sequence covering the time span from the Chalcolithic to Byzantine periods and the other organized both chronologically and thematically. The thematic display includes material from Achziv (an archaeological site on the north coast of Israel), Jerusalem, Cyprus, Egypt, and Etruria. It incorporates an important collection of West Semitic seals, as well as weights, Jewish coins, oil lamps, games and toys, jewelry, and the biblical "seven species." Also included in the collection are examples of Phoenician material culture, an exhibit devoted to ancient crafts and industries and the Ma'agan Mikhael ancient ship. The museum also houses a collection of French impressionist painting and Jewish art from the mid-nineteenth to early twentieth centuries.

Bible Lands Museum, Jerusalem

Located on Museum Row, the Bible Lands Museum was established in 1992 and primarily consists of material from the private collection of its founder, Dr. Elie Borowski (Westenholz and Romano 2002). Intended to provide background for the *Bible*, the museum situates biblical Israel within its wider Near Eastern context, both regionally and chronologically. This is echoed in its floor plan in which the gallery dedicated to Israel is situated in the center of the building, while the other galleries encircle it. The museum contains 20 galleries arranged in chronological order and thematically titled, beginning with "From Hunter to Urban Dweller" focusing on the prehistoric era. This is followed by "The Coming of Civilisation" dedicated to southern Mesopotamia in the late fourth millennium and "Symbolic Communication" containing seals. "Literate Voices: The Beginning of Writing" focuses on cuneiform and hieroglyphic scripts, and "The Pre-Patriarchal World" concentrates on religious life and commerce in the ancient Near East of the third millennium. Next in the sequence are "The Sumerian Temple" and "Old Kingdom Egypt," followed by a gallery displaying Middle Bronze Age weapons. This precedes "The Age of the Patriarchs" outlining the religions of Mesopotamia, Syria, Canaan, and Egypt at the beginning of the second millennium and intended to provide a backdrop for Abraham, and this is followed by a gallery dedicated to the Exodus. Galleries displaying material culture of the Sea Peoples, Kassites, Arameans, and Assyrians flank the central gallery, "Israel Among the Nations," with the galleries assigned to the Persians, the Hellenistic period, Rome and Judea, Roman and Coptic Egypt, and Sassanian Mesopotamia completing the plan.

The Jay and Jeanie Schottenstein National Campus for the Archaeology of Israel, Jerusalem

The Schottenstein National Campus for the Archaeology of Israel is an ambitious project which is not yet open to the public. Situated on Museum Hill near the Israel and Bible Lands Museums, the national campus is a 350,000 ft^2 complex designed by Israeli architect, Moshe Safdie. Incorporating design components evocative of the landscape of archaeological excavations in Israel, the proposed building includes an enormous canopy referencing the ubiquitous black shade cloths used at Israeli excavations, and the floors are numbered from the top downward in the manner of stratigraphical levels. Intended to house the "Archaeological State Treasures" (antiquities excavated in Israel including the most comprehensive collection of the *Dead Sea Scrolls*), the National Archaeological Library, the National Archaeological Conservation and Restoration Laboratories, and the headquarters of the Israel Antiquities Authority (IAA), it will function as the national center for the storage, conservation, restoration, curation, and publication of archaeological material excavated in Israel. It is envisaged that the center will attract international researchers, provide public education, as well as function as a tourist attraction. To this end, it will house a 250-seat theater, an education center, exhibition galleries, and a rooftop exhibition garden. With an emphasis on accessibility, the building is designed so as most of its space will be visible, including the conservation and restoration laboratories and antiquities storerooms. The IAA scientific archives and the archaeological library

will also be open to the public. Financed primarily by private donations, the project also receives some assistance from the Israel Ministry of Finance (Schottenstein National Campus for the Archaeology of Israel n.d.; Pelletier 2017).

The Occupied Palestinian Territories

Gaza Museum of Archaeology

It is a museum established from the private antiquities collection of Gaza resident and construction company owner, Jawat Khoudary. Attached to a hotel and cultural center situated on the coast near the Shati refugee camp north of Gaza City, the museum opened in 2008. It houses 350 objects dating from the Bronze Age to 1967 and the ending of Egyptian administration of Gaza and is intended to showcase the history and multiculturalism of the Gaza Strip (Al-Mathaf 2008–2011).

Palestinian Museum

The Palestinian Museum is situated adjacent to the campus of Birzeit University north of Ramallah on the West Bank. Designed by Irish architects, Heneghan Peng, the museum is the flagship project of the Taawon (Welfare Association), an independent nonprofit organization which provides development and humanitarian assistance to Palestinians. The museum is situated on a 430,556 ft^2 plot and is being constructed in two phases, with Phase 1 completed in 2016. The building is set within extensive gardens that feature both native and adopted plants. The aim of the museum is to be the principal authoritative source of awareness and understanding regarding Palestinian history, culture, and contemporary life, and it aims to strengthen the bonds between Palestinians and those interested in their culture and history. Designed around thematic galleries, the museum focuses upon both past and present-day aspects of Palestinian culture, with a particular specialization on the modern period from 1750 CE to the present day. While based in Palestine, it is a transnational museum with links to international Palestinians centers through satellite exhibitions, its digital collection, and online platforms (The Palestinian Museum n.d.).

Israel: World Heritage Sites

Chemi Shiff
Tel Aviv University, Tel Aviv, Israel

Introduction

Since accepting the UNESCO World Heritage convention in 1999, Israel inscribed nine sites to the World Heritage list (UNESCO 2006: 35). The sites inscribed in the World Heritage list, alongside the sites listed in the tentative list – which numbers 18 additional sites – represent diverse conceptions of national memory. It is possible to divide the sites into four categories: sites reflecting the Zionist modern Jewish heritage; sites reflecting the heritage of minority and non-Jewish groups within Israeli society; sites reflecting a universal heritage; and sites reflecting natural heritage. An examination of the various sites demonstrates a common denominator, one that depicts different aspects of the ongoing attempt to form a unified Israeli heritage.

Historical Background: An Attempt to Form a Unified Israeli Heritage

In the first decades after its foundation, Israeli society stood against internal and external threats: the country was in constant military conflict with the neighboring Arab countries and desperately attempted to cope with the overwhelming numbers of Jewish immigrants (tripling the size of the original prestate population) arriving at the country's doorstep – many of them penniless. Israel faced a dire need to coalesce the myriad groups of differing ethnic backgrounds into a united nation adhering to shared ideologies and objectives through the use of unifying symbols. In many cases, archaeological sites and artifacts served as such symbols, allowing the promotion of a new homogenized national ethos (Elon 1997: 37; Hallote and Joffe 2002: 86–87; Feige 2007: 281). However, this process of unification also excluded various minority and marginal groups within Israeli society, Jewish and non-Jewish, from taking an active role in the construction of the new shared identity.

In recent years, with the development of second and third generation children of the former immigrant groups and of the original Palestinian population, and following Israel's integration of international processes of globalization and social privatization, many minority groups demanded to reconstruct Israeli identity so as to encompass the diverse historical narratives of all segments of society. Moreover, in an ever more globalized society, the ideological need to prove a historic shared identity made way to the utilization of national heritage symbols as economic assets, better adapted to the growing market of global tourism (Bauman 2004; Baram 2007). An examination of the World Heritage list, which – according to its convention – calls for state parties to enlist sites that contribute to a universal heritage (UNESCO 1972), highlights the complex processes that characterize the development of Israeli heritage, maneuvering between the need to empower particular segments of society, the need to preserve a unified cohesive heritage, and the need to depict Israeli heritage as part of a universal one.

Sites Reflecting the Zionist Narrative

Masada: The site, located in the Judean Desert on the rugged cliffs overlooking the Dead Sea, was inscribed in 2001. It was first built as one of the many architectural enterprises that king Herod of Judea (73–4 B.C.E) planned and built. According to the Roman historian, Josephus Flavius, Masada was also the site where the last stand of the great Jewish revolt against the Roman Empire (74–76 C.E) was staged. The siege camp that was built by the Roman army in order to subdue the rebels constitutes the most complete Roman siege camp to have survived to contemporaneity. According to Flavius' report, when the Roman army broke into the stronghold, they found that all the Jewish rebels committed suicide so as to ensure they would die as free men. During the Byzantine period, the site served as a Christian monastery of a highly ascetic nature. It is one of the earliest known Christian monasteries (Netzer 1993). In Israel's formative years, the ethos of Masada served as the core for one of the Zionist movement's most significant symbols of the courage and selflessness needed to establish a national home for Jews, characteristics that were presented as contradictory to the passive and homeless exilic Jew (Zerubavel 1995).

When inscribed as a World Heritage site, Masada was noted not only for its important role in the construction of a national heritage in Israel's early years but also to its importance in the understanding of the Roman world, both through the examination of Herod's architectural feats and through the knowledge obtained regarding the Roman army through the examination of the siege camp. The site was inscribed to the World Heritage list according to criterions 3, 4, and 6 (UNESCO 2000).

The White City of Tel-Aviv: the Modern Movement: Inscribed in 2003, the site consists of the historic core of the city. Generally acknowledged as "the first modern Jewish city of the Zionist movement," Tel-Aviv is often described as one of the main symbols of the new Jewish Israeli culture. Accordingly, both the urban plan and the architectural influences that shaped the city testify to the important dialogue that developed between the Jewish architects who built it. Their dialogue allowed a merging between Modernist architectural styles into a distinct style reflecting the Zionist ideals predominant between the 1920s and 1940s. This had a great impact not only on Tel-Aviv's architectural plan but on other cities in Israel as well. To date, Tel-Aviv is acknowledged internationally as the city with the largest concentration of buildings built in one of the Modernist styles (Bauhaus) of the first half of the twentieth century CE. The decision to inscribe the city as a World Heritage site was based on criterions 2 and 4. It emphasizes the city's importance as a cultural center of the Zionist community while relating to Tel-Aviv's international importance as one of the only existing concentrations of Modernist architectural styles (UNESCO 2002).

The Biblical Tels: Megiddo, Hazor, Beer Sheva: Inscribed in 2005, the archaeological tels of Megiddo, Hazor, and Beer Sheva are considered as the most important in terms of their biblical heritage. Since the early days of Israel, these sites became an important part of the Zionist narrative representing a yearning for the Jewish return to the Land of Israel. The tels – having been resettled time and again due to their strategic locations – span a time period of at least 3000 years. Most important are the strata dated to the Bronze Age and the Iron Age – generally acknowledged as the time periods in which the biblical period occurred. While the strata dated to the Bronze Age are assumedly attributed to the Canaanite Period, the strata dated to the Iron Age are attributed to the biblical kingdom of Judea. In recent years, all three sites have been at the focus of a public and scientific debate regarding the reliability of the biblical stories. This debate has become especially fierce following the introduction of the "low chronology" theory – claiming that archaeological evidence does not support the claim that a united kingdom of Israel existed as described in the Bible (Finkelstein 1996).

As the three sites are connected to many biblical stories that serve as cultural pillars of all Monotheistic religions, they were inscribed as World Heritage sites not only due to their

importance in Jewish tradition but also due to the role they play in Monotheistic religions. In addition, they were also inscribed due to their stratigraphy which exemplifies the cultural continuity that existed between the Bronze Age and the Iron Age. The sites were inscribed according to criterions 2, 3, 4, and 6 (UNESCO 2003).

Necropolis of Beit She'arim: A Landmark of Jewish Revival: Inscribed in 2015, Beit She'arim was added to the World Heritage list due to the ancient Jewish graveyard dated to the second to fourth century CE located in its vicinity, shedding light on the development of Jewish culture following the failure of the second Jewish revolt against the Roman Empire in 135 CE.

Between 74 and 76 CE, the kingdom of Judah revolted against the Roman Empire in what is known as the Great Jewish Revolt. Following the failure of this revolt, the Temple of Jerusalem – the political and spiritual center of the kingdom of Judah – was destroyed. However, the Jewish population was able to recover, and in 135 CE, it launched a second failed revolt. In the aftermath of this revolt, Jews were banned from the city and the Jewish city of Jerusalem was destroyed and rebuilt as a Roman city named Aelia Capitolina. While a Jewish polity was never reestablished until modernity, a vibrant Jewish community was established in the Galilee – in the northern part of Israel today, transforming Judaism and shaping it as it is known today.

As testified through the ancient graveyard located at the site, following the debacle of the Jewish revolts, Beit She'arim developed into one of the important Jewish centers in the region. It was home to Rabbi Judah the Patriarch, the political and spiritual leader of the Jewish people after the failure of the second revolt, whose importance lies in the role he played promoting the changes Judaism underwent following the destruction of Jerusalem (Avigad and Mazar 1993–2008).

As can be attested by the ornamentations on the graves uncovered in Beit She'arim, which include, among others, human figures, and multi-language inscriptions, the graveyard in Beit She'arim also sheds light on the cultural influences the Greco-Roman world had on Jewish culture during this period, creating a unique multicultural atmosphere (Weiss 2010).

The site was inscribed according to criterions 2 and 3. Criterion 2 refers to the ability of the site to illuminate the methods through which Judaism was able to transform itself from a religion whose main rituals were based on pilgrimages to a physical site (Jerusalem) into a dispersed religion that created new rituals that were not dependent on a particular physical space. Criterion 3 refers to the contribution of the site to the understanding of the multicultural nature of this period (UNESCO 2014a).

Tentative Sites: Sites appearing in the tentative list that reflect the Zionist narrative are the ancient triple-arched gate at Dan; early synagogues in the Galilee, Degania, and Nahalal; Jerusalem (Mt. Zion); and Timna (UNESCO 2010: 10–60).

Sites Reflecting the Heritage of Minority Groups

The Old City of Acre: Inscribed in 2001, Acre was added to the World Heritage list due to the exquisite conservation of the city built by the Crusaders (1104–1291) and during the Ottoman Period (1517–1917). Although Acre has been inhabited for the last 4000 years, only during the Crusader period and the Ottoman period did the city serve as an economic and political center.

During the Crusaders period, the city was first captured by Baldwin I, king of the Crusaders kingdom of Jerusalem. The city quickly became an important port city connecting the kingdom of Jerusalem with the European commercial centers. In its heydays it was second in importance only to the capital Jerusalem. Following the debacle at Karnei Hittin, when the Crusaders were vanquished from the country by the Muslim armies of Saladin (1174–1193), Acre was destroyed only to be built again 4 years later as the capital of the second Crusaders kingdom following its recapture by King Richard I (Lionheart) (1189–1199). After the Mamluk conquest of the

land of Israel, Acre was again destroyed and abandoned until the Ottoman Empire conquered the region. During the eighteenth century, Acre became an important political and economic center and continued to serve as such until the British conquest of the region in 1917. In today's Israel, Acre became one the most important ethnically mixed – Muslim and Jewish – urban centers.

The site was inscribed to the World Heritage list according to criterions 2, 3, and 5. Its importance lies in the rare preservation of cities built during the Crusaders Period and the Ottoman Period, and the rare integration between the architectural styles of both periods. Moreover, the archaeological excavations conducted in the city demonstrate the use the Ottomans made of the remnants of the Crusaders city to build their own one (UNESCO 2001).

The Baha'i Holy Places in Haifa and the Western Galilee: The site was inscribed in 2008. The region of the Western Galilee, and especially the cities of Haifa and Acre, is the location of the most holy places for the Baha'i religion, which was founded in 1844. Most notable among them are the shrines of the two founders of the faith: the Shrine of the Bahá'u'lláh in Acre and the shrine of the Báb in Haifa. The site is divided into 11 distinct areas in Haifa, Acre, and the Western Galilee. Each area includes a varying number of sites. Due to the fact that the Baha'i religion is relatively new, it is possible to examine different stages in the religion's development. Thus the conservation of the site can be understood as important not only to the followers of the faith but to all of mankind. The site has been inscribed under criterions 3 and 6 (UNESCO 2008).

The Incense Route: Desert Cities in the Negev: The site was inscribed in 2005. It includes the northern segment of the Incense Route which connected between the Arabian Peninsula and the Mediterranean basin. It was used mainly for the transportation of frankincense and myrrh – aromatic resins which were processed into prestigious perfumes. The urban and economic growth that occurred during the Hellenistic and Roman Period, and peaked during the Byzantine Period, in Palestine, allowed for the growth of prosperous desert cities along the Incense Route. In the past, their construction was attributed to the Nabataeans, a nation of nomads whose center was in Petra. Their knowledge concerning methods of survival in the barren desert assumedly allowed them to monopolize the northern and most important segment of the Incense Route. In a relatively short period, they abandoned their nomadic lifestyle in favor of a sedentary one, quickly becoming an important political and military force (Negev 1979). During the first decades after Israel's foundation, and despite their possible representation of a past heritage of the native Bedouin population, these sites became an important model of the Zionist effort to resettle the barren desert, often describing the Nabatean culture as a continuation of a previous Judean civilization (Shiff 2017). Although contemporary research questions whether the Nabataeans had the political organization required for the control of a territory spanning between Damascus and the Sinai Peninsula (Elliott 1996; Fabian 2005), the four desert cities – Avdat, Mamshit, Shivta, and Haluza – along with other military fortresses along the Incense Route, have been inscribed as part of the World Heritage site according to criterions 3 and 5, emphasizing the opinion that these cities serve as a testimony to an extinct Nabataean civilization (UNESCO 2005).

Tentative Sites: Among the sites named in the tentative list reflecting the heritage of minority groups in Israel are several connected to the history of the Christian religion (the Journeys of Jesus and the Apostles; Sea of Galilee and its ancient sites) and others that are related to the Muslim and Crusader period (Hurvat Minnim, Arbel, White Mosque in Ramle, and the Crusaders Fortresses) (UNESCO 2010: 10–60). Finally, the addition of the site of Liftah in 2015 to Israel's tentative list is noteworthy. Liftah is a site promoted mainly due to the fact that it is the only remaining intact village that presents the architecture and planning of traditional Palestinian villages prior to the debacle of the Palestinian

culture in the 1948 war in which Israel was founded and the majority of the Palestinian population fled or was deported from the country (UNESCO 2015a).

Sites Reflecting a Universal Heritage

Site of Human Evolution at Mount Carmel: The Nahal Me'arot/Wadi el-Mughara Caves: The site was inscribed to Israel's World Heritage list in 2012. The site includes a number of caves located in the southeastern part of Mount Carmel in the northern region of Israel. The caves, which were inhabited for 500,000 years, are one of the most important prehistoric sites regarding human evolution in the Southern Levant. The inscription of the site was made according to criterions 3 and 5.

According to criterion 3, the importance of the site lies in its ability to examine the evolution of modern humans and their relations with Neanderthals. The Mount Carmel caves are one of the southernmost locations in which evidence for Neanderthal inhabitation has been found. Thus, the Mount Carmel caves have become a key site for the examination of the relations between both species and the chronostratigraphic framework of human evolution in general.

According to criterion 5, the elongated inhabitation of the site allows an intricate examination of the development of human culture and technology. Since the inhabitation of the site continued until the Natufian period, research of the site served to illuminate different aspects of the transition of humans from a hunter-gatherer society into a socially stratified sedentary culture as well (UNESCO 2011).

Caves of Maresha and Beit Guvrin in the Judean Lowlands as a Microcosm of the Land of the Caves

The site was inscribed into the World Heritage list in 2014. It is located in the Judea Lowlands and consists of a large complex of approximately 3500 underground chambers that were dug and hewn over a period of 2000 years for different purposes. The site was inscribed according to criterion 5.

This underground system was carved into the soft chalk strata existing in the region. At first, the area was utilized as a quarry. Later, underground chambers were dug into the soft chalk layers. They were used for different agricultural, industrial, and domestic purposes. Together, this underground system has created an underground city, situated under the ancient twin cities of Maresha and Beit Guvrin. The excavation of the site revealed the changes that have taken place in the uses of this system over different periods. Thus, it's importance lies in its ability to shed light on the cultural continuity in this region (UNESCO 2014b) .

Tentative List: Among the sites that have been added to the tentative list in this category, it is possible to mention sites that reflect the influence of the Roman Empire in shaping the region (Beit She'an/ Decapolis and Caesarea). Another site that is part of this category is the village of Ein Karem, located in the outskirts of Jerusalem. It is a village that has continuously existed for 3000 years, since the Iron Age (1000) BCE and until contemporaneity. Among the many cultures that inhabited this village, the nomination explicitly mentions the Palestinian inhabitation of the village until 1948 and the importance of the site in Christianity. According to Christian faith, it is believed that Ein Karem is the site where Mary, while pregnant with Jesus, met Elizabeth, while she was pregnant with John the Baptist. This belief was the cause for the establishment of a number of churches and monasteries in the village of Ein Karem (UNESCO 2015b).

Sites Reflecting Natural Heritage: Israel has not yet inscribed any natural heritage sites. Nonetheless two sites are listed in Israel's tentative list: the birds' migratory routes in the Hula Valley and the unique geological formations of the Makhteshim region (UNESCO 2010: 10–60). The lack of sites in this category is perhaps symbolic of the way Israel – a land rich in diverse

geographical and natural phenomena – is seen, both internally and by the international community, as one whose heritage is primarily dominated by ideological and historical characteristics.

Conclusions

The sites comprising the Israeli World Heritage list are an edifying test case to the continuing efforts of Israeli society to reconstruct its national memory and heritage according to changing ideologies and aspirations. While in Israel's formative years its national heritage was constructed through the use of sites that promoted a homogeneous memory, the World Heritage list serves as a testimony to an attempt of diversifying society's national heritage and to contend with the processes of globalization and privatization of the public sphere. However, the examination of the World Heritage sites and of the people comprising the Israeli World Heritage Committee can also alert to the many groups – such as Israeli Palestinians, but also different Jewish ethnicities – that still have no active role in the discourse regarding the changes that should conspire in Israel's heritage in the coming years. In this regard, it is especially relevant to note that to date, no site boasting a Palestinian heritage has been promoted by the Israeli World Heritage committee to be inscribed into the World Heritage list. Moreover, it was claimed by some that in several instances – such as the case of Acre – the inscription of the site as a World Heritage site was used to further eliminate the Palestinian characteristics and heritage (Davis 2013).

As Israeli society continues to develop, a continued examination of the changes in the sites comprising the Israeli World Heritage list may be most edifying as to the changes occurring in Israeli society.

Italy, Sicily, Malta, and the Lipari Islands: Prehistory

Simon Stoddart
Magdalene College, University of Cambridge, Cambridge, UK

Introduction

The peninsula of Italy stretches from the Alpine mountain regions of the north to the emphatically Mediterranean maritime and mountainous regions of the south. In the presence of the Apennine mountain range, the full length of the peninsula added an important element of verticality that distinctively affected the response of prehistoric peoples. A further geographical variation was provided by the different sizes of the three island groups of Sicily, Malta, and the Lipari islands. Thus, Italy provides a good geographical cross-section against which to measure human response.

Definition

The choice of Italy as a separate geographical region is in many ways modernist. The unity of the Italian peninsula dates to the Roman Republic and the reestablishment of that unity to the Unification of 80 BP (where BP is the standard fixed point of 1950 in all radiocarbon chronologies appropriate for prehistory the subject of this essay). During prehistory, the peninsula is one of three major southern peninsulae in Europe that cut through a regional diversity, based on environmental variation in early prehistory and emerging political identities in later prehistory. To this we can add the islands of Sicily, Malta, and the Lipari islands which have similarly slipped in and out of the definition of what constitutes Italy.

Prehistory can be defined in Italy as starting some 800,000 years BP on the peninsula, but on the islands only in the late Upper Paleolithic (Sicily) or the Neolithic (Malta and the Lipari

islands). In many regions, prehistory effectively continues up to and into the period of the Roman empire, because writing about many peoples, and not only the Etruscans, took the form of an external "ethnography" by the Romans and Greeks. However, in conventional terms, most Italian archaeologists see prehistory ending with the Bronze Age, or at the very latest the first Iron Age, that is at about 2700 BP, reinforced and symbolized perhaps by the foundation of the famous pre-colonial settlement of Pithekoussai (Ischia) by the Greeks. For this reason, this contribution does not cover in any detail the last four millennia Before Present, since they are generally inserted within protohistory by Italian archaeologists.

The chronological definition of prehistory has traditionally been based on the phases of material culture employed elsewhere in Europe (with the addition of the term Epipaleolithic). These material culture schemes have only been gradually replaced by more absolute methods of dating, particularly in the fourth to second millennia BP where typological studies tethered in historical dates have been employed. For the fourth to second millennia BP, the gradual implementation of dendrochronology largely outside the immediate Italian area has gradually affected the traditional dates based on imports. In the Italian peninsula, the Lower Paleolithic marked by the employment of the earliest human tools can probably be dated to something in the order of 800,000 years BP. More complex industries, generally characterized as Mousterian, developed in Italy over the period 250,000–28,000 years BP. This is, in turn, followed by Upper Paleolithic blade-dominated industries and a major feature of the Italian peninsula, Epipaleolithic industries, that generally replace the designation Mesolithic in other parts of Europe.

Key Issues and Current Debates

Hunting and Gathering

There are two sources of evidence for the early occupation of the peninsula: skeletal remains and stone tools. The earliest hominid remains in the Italian peninsula have been dated to 900,000–800,000 years BP at Ceprano (Frosinone), at a similar date to finds in Spain. However, the earliest human pebble artifacts from Monte Poggiolo (Forli) have been somewhat controversially dated to as much as one million years BP. Many secure Acheulean hand axe sites follow in locations such as Venosa (Basilicata), Fontana Ranuccio (Lazio), Marina di Camerota (Campania), and Castel di Guido (Lazio). A particularly well-research site dating to 700,000 years BP is that of Isernia la Pineta (Molise) characterized by more varied stone assemblages (such as denticulates) and faunal remains of animals of varied size (elephant, rhinoceros, bison, deer, bear, and hippopotamus) on possible living surfaces. This site points to relatively systematic and organized hunting activities even at this early date.

The Mousterian industries are marked by some initial regionalization of styles, whose study has tended to dominate research to the detriment of the study of economic and other issues. Two stylistic provinces have been noted north and south of the modern city of Rome. To the north, there were industries rich in razors and to the south a so-called Pontine micro-industry employing pebbles as raw materials. These regional traditions appeared to have become more uniform over time, with the employment of more denticulates, grading into forms more typical of the Upper Paleolithic (burins, scrapers, etc.). In some Ligurian sites, there was the beginning of the evidence of raw material procurement from sources of as much as 50 km away, a tendency that became much more emphatic in the subsequent Upper Paleolithic. All this related strongly to increasing sizes of hunting territories and social communication.

Some evidence has emerged of structured activities for this period. At the Mousterian site of Grotta di Fumane (Verona), a spatial correlation has been shown between hearths and faunal remains, suggesting a systematic process of animal consumption. At Riparo di Molare, a possible hut associated with animal bones and stone tools has been located in one level and in another the deliberate placement of a bison head, which the excavators suggest related to ritual activity.

The arrival of anatomically modern humans probably occurred in the Italian peninsula at about the same time, 40,000 years BP, as in the rest of Europe. In other parts of Europe, the Chatelperronian industry appears to have been a stone tool industry which responded to the encounter between Neanderthal and these new populations. The Uluzzian industry of burins, razors, lunates, and scrapers may have taken that role in the Italian peninsula, although the precise chronology has not yet been established. The density of human occupation within the peninsula was nevertheless still very low, so low that it would have been subject to disruption by early Vesuvian volcanic activity at 36,000 years BP.

The full early Paleolithic or Aurignacian in Italy has been divided into three regional styles accompanied by increased population density and increased exchange of raw materials above 100 km from the source: one centered on the Veneto, a second "classic" type, and a third located more towards the south. Uncontroversial hut structures with hearths have been found in the Grotta di Fumane, and some possible art of the human form dating to as early as 36,000 BP has been also found in the same deposits. The subsequent Gravettian is best known from the site of Grotta Paglicci in the Gargano of southern Italy. The changed lithic styles were accompanied by poorly provenanced female figurines, from both the north and south of the peninsula, and a well-provenanced incision on stone of a wild goat from Grotta Paglicci. These changes in material culture were built on a diversification of economic activity, with regional specializations such as shellfish collecting (e.g., Riparo Mochi (Liguria) or bullrush processing (e.g., Bilancino near Florence).

From about 20,000 years BP, much of the Mediterranean, including Italy from the Veneto to Liguria, Lazio, and Puglia, was characterized by the Epigravettian, in two forms, one dominated by foliates (leaf-shaped tools) and another by *cran* (shouldered) points. This style of lithics continued right down to 10,000 years BP, characterized by geometrics, notably from the Grotta Romanelli of the Salento area. These late Upper Paleolithic lithic styles are contemporary with a considerable increase in formal burial, accompanied by shell headdresses, and multiple inhumation burials, most notably in the Liguria region, but also at Grotta Paglicci in Puglia. The same period in Italy was accompanied by a veritable explosion in portable art incised on bone and stone that extended throughout the peninsula, depicting both human and animal forms. Engraving on cave walls is best known in Sicily both from the Palermo area (Grotta dell'Addaura on Monte Pellegrino) and in the far west of the island in the Cala dei Genovesi caves. The same range of explanations have been advanced for these expansions of artistic expression as for the classic cases of continental Europe, but the main underlying reasons are probably the macro-context of increasing population densities (requiring statements of identity) and the micro-context of more personalized locales of rites of passage which, when taken together, had the effect of making creativity more visible and apparent, even if the biological capacity had been long standing.

Agriculture

The transition towards agriculture is traditionally preceded and sometimes paralleled by Mesolithic industries in much of Europe – although this terminology is largely replaced by the Epipaleolithic or Epigravettian in Italy, some of the same changes are visible in important sequences such as Grotta dell'Uzzo in Sicily. In this sequence, a broad spectrum of hunted and gathered resources including deer, wild boar, and shellfish but also open water fish have been identified. In the north, seasonal variations by altitude have been detected in the Adige valley, concentrating on various mammals and peri-lacustrine fish, eggs, and turtles in the winter months, while hunting upland deer and wild goat in the summer. All these changes were accompanied by much greater population densities drawing on a wider range of resources. These changes were accompanied by an increasing need to mark territorial identity that showed material form in the continued high frequency of burials in locations such as the Trento region, a high-altitude (2000 m.a.s.l) burial in the Veneto region at Mondeval de Sora, and Grotta dell'Uzzo (at least 10 burials).

The adoption of agriculture is generally equated with the appearance of pottery as a proxy for other developments. In broad terms, our understanding is based on radiocarbon measurements in the same context as early impressed pottery styles. Employing these data, the Adriatic and Ionian seas were the main arenas for interaction with the Eastern Mediterranean that led to earlier development in Sicily, southern Italy, and the Adriatic coast of the peninsula (late ninth millennium BP) than the northern Tyrrhenian coast, Sardinia, and Corsica (early eighth millennium BP) or northern central areas of the peninsula (later eighth millennium BP). The main concentrations of early agriculture were to be found in the coastal plains (assisted by lower sea levels), peri-lacustrine zones, and alluvial fans that had lighter workable soils and higher water tables. As agriculture developed in sophistication and diversification, more permanent occupation of upland areas became possible. There has been much debate over the process of take-up of agriculture ranging from externally derived innovation to local development. After a phase of emphasis of locally derived models based on sites such as Grotta dell'Uzzo in Sicily, the balance appears to be moving towards an emphasis on externally derived innovation. As radiocarbon dating develops in sophistication, evidence is emerging at a European level that the adoption of agriculture may have been more perilous than initially thought, accompanied by phases of boom and bust. This pattern may also have applied to the Italian peninsula.

The early Neolithic of the south of Italy is dated by radiocarbon dates to 8050–7750 calibrated BP on the basis of sites in central/southern Apulia (Torre Sabea, Pulo di Molfetta), Basilicata (Rendina and Trasano), and Calabria (Favella). There is also some evidence of penetration into the fertile plain of the Tavoliere (Masseria Candelaro and Coppa Nevigata) at this early date. Among the pottery, there is some distinction into coarse and fine forms, with a prominence of both footed and round-bottomed forms, of often ovoid or tronco-ovoid shape, frequently decorated with impressions of finger, nail, and shell (hence the term impressed pottery). The lithics are blade industries showing strong affinities with Mesolithic-type microlithic traditions. Crops include einkorn and barley. Ovicaprids appear to be dominant among the domestic animals, particularly at sites such as Torre Sabea in Apulia. At other sites like Favella, while there is a similar prominence of ovicaprids, there is a significant presence also of wild animals, species from wetlands and fish. The flint mine of Defensola demonstrates that resource procurement was increasingly organized on a more systematic basis. The internal organization of sites such as Torre Sabea and Rendina included enclosures for animals and hut structures for humans. In the ritual sphere, there is some evidence of intra-settlement burials and figurines.

The later phases of the early Neolithic of southern Italy (c. 7650–7350 BP) show a differentiation of styles perhaps suggestive of the emergence of regional identities, named, in traditional mode, after the main excavated sites (e.g., Lagnano, Masseria La Quercia, and Matera-Ostuni). These regional identities were accompanied by increased exchange activity (notably of Lipari obsidian), increased size, and boundedness of sites (e.g., Lagnano da Piede reaching 5 ha in size with five enclosure ditches). By contrast, burial practices remained relatively low key, at least in their material remains, taking the form of small numbers of inhumations in structures such as ditches and pits, although some limited collective burial has been found at Diga di Occhito (12 individuals).

The early Neolithic of central Italy follows that of southern Italy with a time lag of some half a millennium, commencing on the coast (c. 7550 BP) and then reaching the inner basins of the peninsula. In the later phases such as Catignano on the Adriatic coast, decorative styles became more regionally distinctive. Catignano itself remains one of the more extensively excavated sites over an area of some 200 m^2, revealing superimposed square huts of reasonable size (70–80 m^2). The site is also typical in the presence of a small number of burials in ditches. The Tyrrhenian side of the peninsula was characterized in this early period by impressed and linear pottery as well as by the less decorated

Sasso-Fiorano forms. Settlement organization is best known from the two interdisciplinary studies of Marmotta on Lake Bracciano and San Marco on an alluvial fan in the enclosed intermontane basin of Gubbio; both point to the importance of lacustrine and riverine resources in these early periods. At the same time, the two sites show the substantial presence of domesticated species but also that local communities drew on a wider range of both hunted and collected wild resources.

The early Neolithic of northern Italy was not substantially different from that of the center, although some of the coastal Ligurian sites of Arene Candide may have had an earlier presence of c. 7750 BP. Some regional styles such as that of Vho were distinctive, whereas others such as Fiorano shared elements with the central peninsula. One particularly well-preserved settlement is that of Lugo di Romagna, detected under 14 m of alluvium. Wattle and daub structures were uncovered belonging to a 70 m^2 rectangular structure, with flooring and hearth intact, as well as a dog's foot which may have been a foundation deposit. There is some evidence of expansion away from the primary lowland zones most suited to early agriculture. In the Alpine foothills, at altitudes of up to 800 m, open and rockshelter sites of the Gaban style have been discovered that combine cereal, legume, and sheep/goat with deer.

The Middle Neolithic of southern Italy is denoted by the very distinctive painted and plastic (handle) styles of Scaloria and Serra d'Alto that was followed in the later Neolithic by the Diana (indicated broadly by a red color and trumpet handles) into the later seventh millennium BP. The Tavoliere plain shows the trends towards larger and more densely distributed ditched enclosures. The occupied part of the largest Passo di Corvo enclosure was of at least 28 ha (although estimated to contain an upper limit of only 300 individuals). In addition, this central enclosure was surrounded by much more extensive ditched boundaries which must have required considerable manpower to construct. Rectangular household structures within had an area of about 30 m^2. These trends towards larger settlement areas were accompanied by the first deliberately constructed funerary structures. The most notable of these is that of Arnesano where a small tomb was cut from the bedrock to house a crouched inhumation accompanied by a rare figurine where identity was focused on a rudimentary head. These more formal funerary practices were broadly contemporary with the structured use of caves (painted walls and deliberate deposits), such as Porto Badisco, which were most probably employed for male (?) rites of passage.

The Middle Neolithic of central Italy (from c. 6450 BP) was characterized by the distinctive Ripoli style of pottery on the Adriatic coast, parts of Umbria, and Lazio accompanied also by the presence of arrowheads. The later Neolithic of central Italy, although present, appears to lack the definition or density of other regions. The Middle Neolithic of the north was marked by the distinctive Square Mouth Pottery style (Bocca Quadrata) that also brought a denser occupation of both higher-altitude and wet lacustrine areas (most notably Fimon-Molino Casarotto).

The islands surrounding the Italian peninsula generally followed similar trends during the Neolithic, and many of smaller islands (Malta, Lipari) were first occupied during this phase. Until about 5950 BP, the stylistic trends of Corsica, Sardinia, Sicily, Malta, and Lipari could be fairly closely linked into those already observed for the peninsula itself. The ditched villages of eastern Sicily had a different cultural name, Stentinello, but the populations of the plain of Catania exhibited a similar phenomenon of increasing density and boundedness to those already noted for the plain of the Tavoliere. However, Sardinia had already begun to exhibit trends towards a separate regional identity in the Bonu Ighinu and Ozieri styles, a development that was only noted emphatically elsewhere within Italy in the Copper Age. In these phases, distinctive figurative art and funerary culture began to emerge that indicated the construction of new identities taken to an even greater extreme by the island of Malta in the late sixth and early fifth millennium BP.

Emergent Identities

In the Chalcolithic, in spite of the name of the period – Copper Age – it is not so much the use of copper, which is almost invisible

archaeologically, but the prominence of funerary evidence over settlement evidence that is most pronounced. A series of local identities emerge, more distinctive and materially more visible in some locales, than in others.

In some islands, notably Malta and Sardinia, ritual complexes emerge. In Malta, this takes the form of large complementary monumental complexes for the living and the dead, reaching a climax in the early part of the fifth millennium BP before falling into a disuse apparently decided by the local populations themselves, possibly under some ecological stress, rather than a response to invasion from outside as some early models suggested. In Sardinia, the monumental complex of Monte d'Accoddi in the north of the island dating from about 5650 BP is the most conspicuous example, among a broader proliferation of largely funerary ritual. On the island of Sicily, there are regional styles, principally known from funerary evidence because of the emphasis of scholarly research, such as San Cono-Piano Notaro, Conzo, Piano Conte, Serraferlicchio, and Malpasso, but the fluorescent ritual complexes were not so prominent. Field survey when undertaken such as in the uplands around Troina has found the corresponding evidence for settlement, but this remains under-researched. At the transition between the Chalcolithic and the early Bronze Age, the presence of Bell Beakers added to the range of emergent identities.

On the peninsula itself, the traditional substantially funerary styles can be reinterpreted as nodes of identity focused on differentiated variations of performative action, which principally, but not exclusively, materialize in death rituals. In the south, there is the fundamentally funerary identity of Laterza. In the area around Paestum and more broadly the region of Campania, there is the funerary identity of Gaudo, distinguished by small collective tombs with leather-like skeuomorphic vessels and large daggers in flint and copper. In central Italy, there were the collective tombs of Rinaldone, containing copper daggers and thin-necked ceramic vessels. In the Brescia region of northern Italy, there were the collective tombs of Remedello, containing another codified ritual of inhumations with flint and copper daggers. This was not the only expression of identity in precisely defined locales. In the Trento region (e.g., at Arco), in the Aosta region, and in the Luni region of northern coastal Tuscany, there were concentrations of menhir figures depicting human identities, and in the Val Camonica and Valtellina regions, rock art that filled a similar role. In one unique case, we have a well-preserved survival of one individual, the iceman who moved in these worlds giving a detailed but not necessarily representative insight into the lifestyles of populations in the course of transition between the world of the Neolithic and that of the Metal Age. The arrival of more widely used metal brought an end to this type of display of identity and brought another that was based much more on economic fundamentals, accumulation, and corresponding deprivation, a form of expression of identity that took a good millennium or more to put in place.

New Economies

The development of the full Bronze Age in the course of the fourth millennium BP brought a new type of both portable wealth (bronze itself) and wealth tied to the land (the arboriculture of Mediterranean polyculture (grain, vine, and olive)). Both these features took off relatively slowly compared with the Eastern Mediterranean and more slowly in central Italy than in the south. The terramare of northern Italy did exhibit an intense development in the first half of fourth millennium BP, but at about 3150 BP, the population appears to have suffered a substantial decline. The greater storage of wealth may partly explain the more prominent materialization of nuraghi in the Bronze Age of Sardinia and the distinctive cultural phases of Sicily. A further factor was increased connectivity with the Eastern Mediterranean. Sardinia was clearly in regular contact with Cyprus at least by the recent Bronze Age as shown by the prominence of ox-hide ingots. In Sicily, the settlements of the Thapsos phase which succeeded the villages and cemeteries of Castelluccio were clearly in contact with the Mycenaean world. However, central Italy was substantially outside the range of these developments, and only in the Final Bronze Age did a

vibrant village life take off in a substantial way, with considerable mobilization of bronze technology. It was this momentum that continued into the periods of state formation that followed, resisting the colonization that affected southern Italy and the surrounding islands. Recent work has shown the fundamental importance of the Final Bronze in establishing the sociopolitical context that was receptive to entanglement with other parts of the Mediterranean in the early stages of the third millennium BP.

Future Directions

Overall Trends and Debates

The key issues and current debates that transcend these chronological stages center on the reconstruction of subsistence, the measurement of interaction, and the emergence of regionalism, first as a statement of identity and then as a projection of political hierarchy. Until the 1980s, much work on Italian prehistory was focused on the construction of local culture histories. In the current century, much work is emerging which is making major strides on all these issues. Our understanding of subsistence can now follow the transitions from hunting and gathering through the differential take-up of agriculture to the political orchestration of Mediterranean polyculture at the close of prehistory directed towards feasting on the one hand and the less recognized mobilization of infrastructural support of large urban populations on the other. In parallel, scholars can follow the increasing potential levels of interaction as the use of the sea around the peninsula (and the major rivers through the peninsula) moved from simple technologies that carried relatively small quantities of material while hugging the coast to large-scale transport of subsistence products often moving out of sight of land. During the course of these technological developments that included the incorporation of the production and use of bronze and iron, the massively increased infrastructural support led to the emergence of regional differences, specializations, identities, and ultimately political divergence. In the south of the peninsula and the major islands, interaction with Greek and Phoenician communities became a substantial part of the political dynamic. In the center and north of the peninsula, independent but entangled urbanisms emerged that rivaled the size and political power of those from the East. One of these, the Latin and then Roman, ultimately became master of much of Europe, by a more effectively implemented political trajectory that combined superior centralization, incorporation of subgroups, and physical force.

Italy: Medieval Archaeology

Gian Pietro Brogiolo
Universitá Degli Studi di Padova (University of Padua), Padova, Italy

An archaeological study of the Middle Ages appeared in Italy, as in other European countries, between the end of the nineteenth and the commencement of the twentieth centuries. Italy, which was reunited politically in 1861 after 1,300 years of division, was seeking its identity during the era of communes which had defeated Emperor Frederick I of Germany (Frederick Barbarossa). During the Fascist period (1922–1945), these still timid approaches disappeared from the scene due to the fact that they concerned a historical period considered in decline in comparison with the glories of the Roman Empire. However, Paleochristian Archaeology, with its focus on Late Antiquity, during which Christianity had begun, did not undergo any form of reappraisal. Following this interval, it was the historian of law, Gian Piero Bognetti, who in 1958 proposed a re-establishment of Medieval Archaeology. Between 1958 and 1963, he personally undertook excavations at Torcello (Venice) and Castelseprio (Varese), entrusting the work to a team (under the direction of Eleonora Tabaczynska and Stanislaw Tabaczynski) who hailed from the Institute of Material Culture in Warsaw. After Bognetti's death (in 1963), the excavations at Castelseprio continued through the efforts of a young team of people who had been assisting with the research.

During that time, Nino Lamboglia was pursuing his work on stratigraphy in Liguria, with research having commenced in the 1930s. In the meantime, between 1958 and 1962, Gaetano Panazza, director of the Civici Musei of Brescia, was excavating the Church of San Salvatore of Brescia, assisted by one of Lamboglia's students. It is therefore not surprising that in 1966, through the initiative of Michelangelo Cagiano de Azevedo, a scholar of Late Antiquity, the Catholic University of Milan established the first Italian Chair in Medieval Archaeology, followed by the establishment of a school of specialized studies which was extended to studies in Late Antiquity and the early Middle Ages. This historical period was a focus of interest in Lombardy, with work being undertaken by leading historians and archaeologists active at the time, and in particular the history of the Longobards, following the example of studies carried out by Gian Piero Bognetti and Gaetano Panazza, experts on the history of Milan and Brescia.

Subsequently, in the 1970s, this research environment saw the introduction of the innovative methods based on English urban archaeology, imported to Pavia, the ancient capital of the Longobards, through the efforts of Adriano Peroni, a pupil of Panazza's and director of the local museum. In fact in 1972, he entrusted to two young English archaeologists (Hugo Blake and Brian Ward-Perkins) firstly the excavation of the Torre Civica and subsequently an ambitious project in urban archaeology. Following on from these experiences in Pavia, and enriched by the technical contribution of Martin Carver who was invited to deliver courses to archaeological practitioners at Botticino (Brescia) from 1979

to 1982, the period of major urban excavations developed in various Italian cities at the commencement of the 1980s.

For their part, in 1973 the Tabaczinskis return to carry out new excavations in Italy (at Capaccio Vecchia, Salerno), as a result of which, a new group of medieval archaeologists is formed (Paolo Delogu, Paolo Peduto, Gabriella Matzke).

However, in 1971 a turning point in theoretical-methodological approaches is marked by the group in Genoa directed by Tiziano Mannoni, a student of Lamboglia's, with the publication of the "Notiziario di Archeologia Medievale" [Bulletin on Medieval Archaeology]. This group integrates the study of historical geography, promoted by Massimo Quaini, with the positivist tradition of Italian prehistorians (active in Liguria with Luigi Bernabò Brea) and the International Institute of Ligurian Studies of Nino Lamboglia, all of which combine with the neopositivist and neomarxist tendencies reproposed during the experiences of the student uprisings of 1968.

The encounter in 1973 at Scarperia (Florence) with the Tuscan group led by Riccardo Francovich sees the emergence of the journal *Archeologia Medievale* [Medieval Archaeology] which, in the editorial of the first issue (1974) written by Massimo Quaini, proposes an archaeology of the material culture of subaltern classes that is socially and politically engaged in the preservation of cultural heritage. Such a direction marked a departure from Classical Archaeology viewed through the lens of historical-artistic expression, and Christian Archaeology expressed through Catholic ideology linked to the Vatican. Further deepening this rift was the enthusiastic support shown in the stratigraphic discoveries being experimented in the 1970s by English archaeology. In this frame, two valued proponents were Andrea Carandini and Daniele Manacorda, both of whom, like Riccardo Francovich, were lecturing at the University of Siena. As archaeologists of classical training but with links to Anglo-Saxon experiences, they diffused these methods at the commencement of the 1980s: the former by means of a manual on stratigraphical excavation (Carandini 1981) and the latter with a translation in 1983 of *Principles of Archaeological Stratigraphy* by Edward Harris.

In the 1970s, very little was known in Italy about the material culture of the Middle Ages, such as settlements with wooden dwellings, as with fortifications, manufacture, and commerce. Therefore, the first objective of the various groups of archaeologists was to set up information categories for each strand of research. Early on, the reference points were above all the works of French scholars on the history of the *longue durée* developed around the *Annales*: from *The Mediterranean and the Mediterranean World in the Age of Philip II* by Fernand Braudel to the history of the town of Montaillou during the Inquisition by Emmanuel Le Roy Ladurie and the history of the landscape of the Sabine (in Lazio) during the early Middle Ages outlined by Pierre Toubert with documentation of the monastery at Farfa. During this time, archaeological research agendas, above all in Tuscany, were oscillating between scholars of medieval deserted villages and scholars of the second generation of castles (between the tenth and twelfth centuries).

In 1981, a conference held in Pavia ("Archeologia medievale: il prossimo decennio," *Archeologia Medievale*, X, 1983) ["Medieval Archaeology: the next decade," *Medieval Archaeology*, X, 1983] led to comparisons between medieval archaeologists working in Lombardy with those operating in Tuscany-Liguria. The conference marked a turning point in Italian medieval research. The moment was favorably inclined for the diffusion of new ideas since that year a dozen officials in medieval studies were taking up positions in government departments, while in the universities teaching in the discipline was beginning to spread. The major excavations in Brescia, Milan, and Verona not only triggered a debate on the methods and views of urban archaeology but also supplied work on the first archaeological projects based on the English model, endeavors that opened up a third professional pathway for archaeologists, besides those in universities and government departments. In research carried out on medieval landscapes, apart from excavations of dwellings,

surveys of wider territory were begun, during the course of which, aerial photographic interpretation and reconnaissance methods were systematically applied.

Following on from this were excavations of castles, both those of Late Antiquity such as Sant'Antonino of Perti in Liguria, Castelseprio and Monte Barro in Lombardy, and those of the second generation (from the tenth century onward) such as Rocca San Silvestro and Poggibonsi in Tuscany. Above all, Monte Barro signaled a shift, thanks to the systematic application of those scientific branches in archaeology that at the time were defined as paleobotany and zooarchaeology and through which reconstructed the environment and eating habits of the castle residents from the fifth to the sixth century (Brogiolo and Castelletti 1991).

In that same decade of the 1980s, Medieval Archaeology was also dedicated, through salvage rescue excavations, to the study of churches, thus extending stratigraphical methods, as well as the study of burials and the settlement context. Among the most significant were the excavations of Longobard monasteries, such as San Vincenzo al Volturno (founded by the Dukes of Benevento) and San Salvatore of Brescia (founded by King Desiderius and his wife Ansa). These studies were no longer limited by the "Paleochristian" period but were extended to the entire life span of the edifices. Similarly the necropolis were finally taken into consideration independently from the study of burial objects.

The flourishing of all these disciplinary specializations entailed the formation of specialist fields: geomorphologists and sedimentologists for the interpretation of stratified deposits and those studying techniques of production, various types of craft, and biological remains. During this period, the standard-bearers of these specializations were Tiziano Mannoni based in Genoa and Lanfredo Castelletti in Como.

Midway through that decade of significant development, emanating from a branch of urban archaeology, the building archaeology of architecture was finally developed in numerous centers (Genoa, Siena, Brescia, Venice, and finally Milan) through a collaboration with restoration architects. The official manifesto was created in 1987 at the Summer School of Pontignano near Siena (Francovich and Parenti 1988), and the following year the first handbook appeared (Brogiolo 1988).

In conclusion, the 1980s were a period of consolidation in the institutions and among professionals for the development of specializations and research methods in different disciplinary sectors with the intention of exploring the entirety of material culture in the Middle Ages.

The subsequent decade, which entailed discussion and rethinking on the basis of the knowledge acquired, opened in 1992 with a conference organized at Pontignano (Siena) by Riccardo Francovich with the collaboration of Ghislaine Noyé (Francovich and Noyé 1994). The title (*La storia dell'alto medioevo italiano alla luce dell'archeologia)* [The history of the Italian early Middle Ages through archaeology] synthesized the focus of research conducted to that point: constructing material sources that could communicate on equal terms with written sources but with a focus only on the early Middle Ages which, after the 1970s and above all thanks to the debate on cities of that period, had been cast in the spotlight.

Around the mid-1990s Medieval Archaeology was enriched by two new reference points: the "Società degli archeologi medievisti italiani" (SAMI) [the Society of Medieval Italian Archaeologists] (founded in 1993) and the journal "Archeologia dell'Architettura" [Archaeology of Architecture] (whose first issue appeared in 1996).

The role of SAMI emerged as an important one, more than for its institutional interventions, thanks to a few initiatives pursued over the time: the national conferences on medieval archaeology held triennially at various locations from 1997 onward; the Ottone d'Assia Prize (later also dedicated to Riccardo Francovich) awarded to a publication by an early career researcher, totaling 15 volumes printed from 2000 onward; the Riccardo Francovich Prize for the best park or archaeological museum with a medieval theme;

and the series "Metodi e Temi dell'Archeologia medievale" [Methods and Themes in Medieval Archaeology].

The need for a journal on "Archaeology of Architecture" arose, instead, from a prolonged debate with restoration architects with far-reaching interest even in Spain, where in 2002 a similar journal was established ("Arqueología de la Arquitectura"). The discussion continued in the first decade of the twenty-first century through comparison with structural engineers who adopted the methodologies of archaeology of architecture in the guidelines for interventions on historical buildings. More recently, following on from quantification work carried out by Janet DeLaine on the public architecture of the Roman era, even a group of classicists has finally adopted stratigraphical methods, and the journal, which has always existed without restrictions on specific chronologies, has also welcomed their contributions.

Between Archaeology and History: Some Themes in the Debate

The initial themes of the debate were set predominantly by historians in disciplines like medieval archaeology, which is concerned with a period that historiographical conventions identify from 476 (marking the end of the Western Roman Empire) and 1492 (the year of the discovery of America by Christopher Columbus). This is because they enjoyed a long tradition of study, and in the academy, up until the 1970s with few exceptions, courses on the Middle Ages were delivered by historians and art historians, and therefore the earliest medieval archaeologists had received that training. Furthermore, up until the first decade of the new millennium, the influence of Christian Archaeology remained entirely marginal, even though it had a long and uninterrupted tradition of scholarship.

After all, the new discipline had not yet developed a sufficient level of maturity to formulate its own research strategies, a maturity acquired through debate on certain themes. The first debate, in the second half of the 1980s, concerned the interpretation of initial data offered by urban archaeology in Brescia and Verona – two cities that had enjoyed success in the early Middle Ages and could therefore proffer a yardstick for urban studies of that period.

The Debate on the Transformation of the City

The debate on the evolution of the city in the early Middle Ages, which was widespread and the subject of presentations by leading archaeologists and European historians, had its origins in an article published by Cristina La Rocca in 1986 in *Archeologia Medievale*. Contrasting with my pessimistic interpretation based on data from studies of urban archaeology in Lombard cities, particularly Brescia, was an optimistic vision of the evolution of the ancient city on the basis of written sources from Verona in the ninth and tenth centuries. The discussion continued, then, in the second half of the 1990s, based on data that urban archaeology was gathering in many cities (a synthesis is available in Brogiolo and Gelichi 1998). In Rome, specifically, this is due to the excavations of the Balbi Crypt (conducted by Daniele Manacorda), of the forum of Nerva (conducted by Riccardo Santangeli Valenzani and Roberto Medeghini), and many salvage urban excavations, memorable among which is the recent one in Piazza Venezia which has highlighted an important artisan district. In Naples, the subject of numerous excavations, the most significant data is that obtained on the port, as well as an admirable synthesis by Paul Arthur. At Cividale and Ravenna, the former is the seat of a regional Longobard duchy and the latter a Byzantine exarchate. Apart from the transformation of the urban landscape, the debate has highlighted the economic, social, and cultural aspects of the so-called age of invasions/migrations, at the center of the project on the *Transformation of the Roman World* funded by the European Science Foundation.

The Debate on the Countryside

The debate on the transformation of the countryside in the early Middle Ages developed later,

during the 1990s of last century and the first decade of the current century, following numerous studies conducted in Tuscany and in northern Italy, which have given rise to two contrasting models.

In Tuscany, excavations carried out by Riccardo Francovich and later Marco Valenti below second-generation castles (constructed, as previously stated, from the tenth century onward) have uncovered phases of settlement from the early Middle Ages. Following the concept of a peasants' golden age proposed by Chris Wickham, these phases have been interpreted (Francovich and Hodges 2003) as an early concentration of the population on high ground, commencing at the end of the sixth century. Such a concentration would have been brought about by peasants who liberated themselves from the control of the aristocracy in the previous phase of the breakup of the Roman settlement, centered on villas.

On the contrary, in northern Italy, where most of the information was derived from castles constructed in the fifth to the sixth centuries and from villas that demonstrated meagre settlement phases, the interpretation suggested both a persistence of sparse settlement and the maintenance of strong hierarchical control over the land (Brogiolo and Chavarría Arnau 2005).

At the commencement of the 2000s, these divergent views were discussed at various conferences (among which Brogiolo et al. 2005; for a synthesis of the debate: Valenti in Gelichi 2014, 123–142) which proved fruitful in defining plans for future research. The notion of a period of breakup, no longer under hierarchical control, and defined as "chaotic," has moreover been superseded even in Tuscany when excavations began on villas and below second-generation castles, where evidence of hierarchization was brought to light, such as in Miranduolo, a village constructed on a mining area under public control since the seventh century.

The Longobards

In Italy, discussion on the effects of the Longobard invasion has been one of the most pursued topics by medieval archaeologists with opposing views. Interest in the Longobards – which has given rise to no less than four major exhibitions in the last quarter of a century – depends on the fact that in Italy, the Longobards bring to an end the unity of Italy which was still present during the Gothic period, when the peninsula was part of a political and economic power system that stretched from the Adriatic to Hispania. In fact, Italy found itself fragmented among territories reconquered by the Eastern Romans and the duchies of the kingdom, often autonomous when not fighting among themselves. There was a marked fragmentation in the ninth century, from the Arab conquest of Sicily, destined to last until 1861. It is therefore not unusual that the Longobard question has always been at the center of the historiographical debate from the time of Machiavelli and Guicciardini (at the beginning of the sixteenth century). Even today much attention is dedicated to it, at the cost of other themes and periods of Italian medieval history.

As in other countries, the debate has been particularly fiery in the 1990s of the last century and in the first decade of the present century. On the one hand, those commencing with the presupposition that burial objects do not provide proof of an identity maintain that there was an evolution predominantly within late Roman society. Others, placing major faith in what they attribute to sources, propose views that are diametrically opposed, based on a strong identification of the invaders which has been maintained for a long time as a result of the permanent conflict with the Eastern Roman Empire.

We have now entered a crucial phase of research, thanks to new and important excavations of necropoli with burial objects, among which is worth noting those at Ovada and Collegno in Piedmont, at Spilamberto in Modena, at Fara in Bergamo, and at Cividale in Friuli. This is, above all, thanks to DNA analysis and isotopes of skeletons which are confirming the traditional model that associated burial objects with weapons of the Longobard elite.

Of Christian Archaeology and Medieval Archaeology

Christian Archaeology has enjoyed a very long tradition since the time of quests for the relics of

martyrs. Until the 1970s it has, however, mainly adopted the specification of "Paleochristian" in order to observe the principal objective of studying the origins of Christianization through excavations and the study of places of worship with their rich decorative display. A point of division among historians of Christianity was interest in ecclesiastical structures, the liturgy, and the lives of saints. The introduction of officials in medieval studies in government departments, commencing in 1980, has largely broadened research themes on churches. However, common interests, such as training, curricula, journals, conferences, and referring institutions, have remained distinct.

Moreover, have been important research projects on churches carried out by medievalists and the publication of a handbook on the archaeology of churches (Chavarría Arnau 2009). A collaboration then developed around the Corpus Architecturae Europeae (CARE) (http://arcmed.lettere.unipd.it/CatMedievale/CARE_IT_HOME.html), an undertaking which is revealing itself as a prime opportunity to reinvigorate research. Thanks to the number of churches, continuity of their use, and the survival of architecture and handcrafted articles, a broad amount of information is in fact on offer, not only on the ecclesiastical network but also on the settlements, society, and ideology of the entire medieval period.

The First Decade of the Twenty-First Century: A Phase of Reformulating Medieval Archaeology

At the beginning of the twenty-first century, a phase of reformulating Italian Medieval Archaeology has taken place, influenced by multiple factors, not only as a result of comparison with scholars from other medieval studies disciplines but above all in relation to problems within the entire archaeological field.

In addition, a serious influence results from changes to legislation, particularly from the enactment of the *Codice dei Beni Culturali* [Cultural Heritage and Landscape Code] in 2004. This repressive Code has placed the entire Italian archaeological research world, not only medieval archaeology, at the mercy of bureaucrats from the Ministry of Heritage, Culture, and Tourism who, in fact, exercise full control not only over its protection but also in terms of archaeological research which in Italy is subject to approval in the case of excavations and authorization in the case of research and publication.

The loss of Italian archaeology's credibility is further worsened as a result of general crisis factors, also common in other countries, that are the consequence of our current historical era. Globalization is erasing national cultures and local identities, removing from archaeology the social function of constructing historical memory in which local communities can recognize themselves. A further outcome is the loss of value in cultural heritage in a society evermore flat and disinterested in its own roots, for which the only alternative now seems to be a turning of the past into a Disneyland-style spectacle.

Apart from this cultural regression, there is also the economic crisis which has struck more severely in Italy than elsewhere, rendering the survival of archaeologists more difficult. From a small group of a few dozen trained professionals in the 1970s, 30 years later the number had reached a peak, now downsized, of at least six to seven thousand people making a living from archaeology.

It is therefore in this context of an internal malaise of the whole archaeological sector, and the loss of values that were considered firmly in place, that Medieval Archaeology, the weak link in the entire chain, must measure itself. In a previous reflection (Brogiolo 2009), I maintained that in order to overcome the crisis, Italian medieval archaeology needed firstly to liberate itself from the guardianship of historians who, for 30 years, had proposed the research themes and the interpretive points. Other models, based on material data, needed to enter the research agendas of medieval archaeologists, for example, the reconstruction of environmental evolution, landscapes of production, bioarchaeology, and physical anthropology. For these, as with other themes, I also asserted how it was advisable to move away from the restricted chronological

constraints of the Middle Ages (as indeed the early Middle Ages) in order to tackle the *longue durée* and interdisciplinarity. This was the path of a "global archaeology," upheld by Tiziano Mannoni since the 1970s and which more recently had become the battle horse of Giulio Volpe in advocating for a reform of heritage protection. This involves a diachronic and interdisciplinary archaeology to be carried out using a complex approach in which historical landscapes represent the context from within which one can survey the systemic interrelationships between elements and spaces of production, settlement and the sacred. In this archaeology of complexity, the objective is to overcome both determinism and "idealistic" reconstructions, even more removed from reality.

An approach of this type is firstly dealt with at a local level, since it is based on a systemic gathering of all the information. The selection of local communities as a setting for the research highlights the social function and proposes a "political" role to an archaeology that, closed within itself, had never possessed it or had lost it along the way. The result, however, is not that of a local story: repeated across many areas, it allows more general syntheses and allows us to understand the biodiversity through which communities of the past were preserved for millennia. It therefore makes us cognizant of how much they have lost through the uncontrolled evolutionary process in which we have placed ourselves without knowing where this will land.

The conclusion was that only by signaling new themes would archaeology in general and medieval archaeology in particular be assured of a future. But for this objective the discipline had to reinvent itself in order to preserve the role of stimulus and action that it had occupied from the 1970s to the 1990s of the last century.

Moving on from these conclusions, while still maintaining the codirection of "Medieval Archaeology" and "Archaeology of Architecture" to which I have continued to remain committed, in 2010 I decided to found, with Alexandra Chavarría Arnau and the support of other Italian and foreign archaeologists, a new journal: *European Journal of Post-Classical Archaeologies*. The editorial of the first issue, which appeared in 2011, in line with critical reflections that had matured in the preceding years, underlined the objectives: diachrony, interdisciplinarity, internationalization, centrality of archaeological data and interpretation without the influence of other disciplines, and attention paid to new themes and discussions. In the subsequent issues, the following themes were explored: GIS and spatial analysis, bioarchaeology and the potential and limitations of isotopic analyses, marginal landscapes and economies, disaster and resilience, recycling and reuse in the Middle Ages, and rivers and waterways. Moreover, in the Dossier section, the following were discussed: Public Archaeology, Protection and Freedom of Research, Communication and Open Access in Archaeology, World Heritage and the Public, Anticommons in Cultural Heritage.

Challenges for the Future

In 2014, on the fortieth anniversary of the foundation of the journal *Archeologia Medieval*, a series of theoretical-methodological reflections on Italian medieval archaeology were published. What emerges is a picture that remains vital, evidenced by the large number of important projects in progress and in part already published and by the salience that research in southern Italy has achieved.

While it is impossible to cite them all, I would at least like to note the following: for central-northern Italy, the research in Venice, as a continuation of work carried out in Comacchio (Sauro Gelichi); in Piedmont and Lombardy (under the supervision of government departments); in Liguria (Philippe Pergola and the local bureau); and in Tuscany (Marco Valenti, Federico Cantini, Giovanna Bianchi) comprising a full excavation of the mining village of Miranduolo. And, among many projects under my direction, I will limit myself to noting the one on the landscapes of the Trentino (2008–2013) which, also bearing in mind successive developments, has so far resulted in a total of 14 published volumes.

Additionally, there are numerous and important other research projects in southern Italy, and I will limit myself to mentioning the systematic ones supervised by Giulio Volpe (with the large-scale excavations of San Giusto, Faragola, Canosa) and by Paul Arthur in Puglia; those of Federico Marazzi at San Vincenzo al Volturno and the churches in Campania; in Sardinia those of Marco Milanese at Geridu and of Giorgio Spanu at the ports; and the work by Rossana Martorelli in the byzantine quarter in the center of Cagliari.

Italian medieval archaeology therefore continues to express strong project designs, but there are at least four challenges, three of which are interconnected and relate to all of Italian archaeology.

The first challenge derives from the reform of the system of protection which, after more than a century of independence, has incorporated archaeology within the framework of a unique supervision that also includes landscapes, monuments, and historic and artistic cultural assets. This choice, steered by politics with different motivations, has, from the theoretical point of view, certainly been supported by the "global" approach in research. And with this outlook, all the archaeological disciplines constructed as silos should be measured.

The second challenge concerns the redesign of university education, modelled 20 years ago by the exclusive interest of lecturers who multiplied the degree courses, resulting in a flood of graduates with limited professional training, who are unemployed or carrying out other types of work.

The third challenge, on which the future of all archaeology depends, lies in the rediscovery of social meanings that will transform it from a constraint/obligation imposed by the State and valued by a small minority of citizens (no more than 5% on the basis of analyses that have been conducted) to being able to reconstruct a lost Italian historical memory. From this viewpoint, defined as "public archaeology" or "social archaeology," multiple lines of research are active. The most effective is, however, the one that constructs the agendas and realizes them in collaboration with local communities and is attentive to the themes of biodiversity and the sustainability of the past in relation to the present.

In this view, medieval archaeology, with respect to other disciplines, seems, at least potentially, more prepared: it is concerned with a period closer to us and is used to dialoguing with other sources and disciplines. However (and this is the fourth challenge), it must open itself up, in diachrony, to what comes before and after the Middle Ages, which means taking up the themes of the *longue durée* using interdisciplinary and diachronic methods. These themes flow outwardly from the environment to anthropic landscapes to architecture and technologies. And they are all found within the history of individual rural communities, from a territory's phase of conquest until today.

Moreover, in order to safeguard its identity and reason for being, medieval archaeology must continue to investigate themes dealing with economic trends, inventing new themes from among available material data in order to compare with written sources. By way of example, I can recall three: the history of cities from the eleventh century onward reconstructed via their urban evolution and the large number of elevated buildings still preserved (an example is Padua: Chavarría Arnau 2011); castles of the second generation and churches, between the Ottonian era and that of the Swabians, as an expression of the dynamics of regional power at the center of which, against the setting of the tortuous relationships between the Papacy and Empire, one is aware of the influence of ecclesiastical hierarchies and the high-ranking officials of the empire; and the strengthening, in the late Middle Ages, of regional markets whose rhythms are to be patiently reconstructed following road networks and river routes. From these and from many other themes, diverse narratives will emerge with respect to those that we can presently narrate utilizing only written sources.

Furthermore, in dealing with the end of the ancient world and the period of invasions, we must set our objective by placing Italian history in a European context, because in that scope political dualism operates (of the Papacy and the Empire). The end of the Middle Ages, besides

the discovery of the Americas, and the consequent shift of the economic and commercial center of gravity from the Mediterranean to the Atlantic, is signaled also by the crisis of these two powers. The Papacy will lose control of the Church of England and northern Europe; the Empire will be substituted by nation states.

Italian medieval archaeology, facing these themes that have been left too frequently to historians reliant on written sources, architecture, and the arts, should be tied to the modern era and from there to current problems, in a diachronic course that could make a very original and comprehensible contribution, even for those who are experiencing a further, even more profound, period of change.

Appendix. Handbooks and Summary Volumes

A history of Italian Medieval Archaeology has until now been tackled by some archaeologists who have been its protagonists; what is missing, therefore, is a detached historical reconstruction which will be the task of a future generation. Moreover, this is not a simple undertaking since there has been a simultaneous development in numerous centers that have not always been attentive to the dissemination of their work.

Since the end of the last century, attempts at a comprehensive history can be found in the handbooks of Sauro Gelichi (1997) and Andrea Augenti (2016). On the phase in the 1970s, one can read the testimonies of David Andrews, Hugo Blake, Gian Pietro Brogiolo, Richard Hodges, Sauro Gelichi, Guido Vannini, and Brian Ward Perkins in the dossier published in the journal *European Journal of Post-Classical Archaeologies* (1, 2011, 419-498). A reflection on the methods and views of the historical group that referred to Riccardo Francovich and Tiziano Mannoni can be found in "Quarant'anni di Archeologia Medievale in Italia" [Forty Years of Medieval Archaeology in Italy] (Gelichi 2014) and in number XLI of the journal *Archeologia Medievale* dedicated to Tiziano Mannoni.

Among the volumes on single themes, developed mostly on the basis of material data but also keeping in mind other sources, see those on the castles of the first generation in northern Italy (Brogiolo and Gelichi 1996); the city in the Italian early Middle Ages (Brogiolo 2011); monasteries of the early Middle Ages (Marazzi 2015); the countryside (Brogiolo and Chavarría Arnau 2005); and churches (Chavarría Arnau 2009).

The following contain syntheses on individual themes: the Summer School of Pontignano and the series "Ricerche di Archeologia Altomedievale e Medievale" [Archaeological Research of the Early Middle Ages and Middle Ages] (published by Insegna del Giglio, Florence); "Documenti di Archeologia" and "Progetti di Archeologia" (SAP, Mantua); the volumes of the "Centro interuniversitario per la storia e l'archeologia dell'altomedioevo" [Inter-university centre for history and archaeology of the early Middle Ages] (Brepols); the conferences held at the University of Foggia in southern Italy and the "Giornate Gregoriane" [Gregorian Days] in Agrigento (volumes I–X) (Edipuglia, Bari); and the conferences on the "età romano-barbarica" [Roman-barbaric age] of Cimitile (Naples) and "Archeologia Barbarica" [Barbaric Archaeology] in Milan (Giostra 2017).

Among the occasional conferences, which are useful for the discipline to grow, apart from those at Pavia in 1981 and Pontignano in 1992, it is worth remembering those held in Ravenna in 2004 on cities (Augenti 2006), in Trent on Longobard necropoli (Possenti 2014), and in Rome on manufacture (Molinari et al. 2016).

Triennial updates on research can be found in the proceedings of the eight "Congressi nazionali di Archeologia medievale" [National Conferences on Medieval Archaeology] (from 1997 to 2015),

promoted by the "Società degli archeologi medievisti italiani" [the Society of Medieval Italian Archaeologists].

Jaffa and the Jaffa Cultural Heritage Project

Aaron Burke[1] and Martin Peilstöcker[2]
[1]Near Eastern Languages and Cultures Department, UCLA, Los Angeles, CA, USA
[2]Humboldt Universität zu Berlin, Kelsterbach, Germany

Introduction

Jaffa (Canaanite *Yapu*; Heb. *Yafo*; Gk. *Joppa*; Ar. *Yafa*) is situated south of the modern city of Tel Aviv on the coast of Israel between Caesarea Maritima and Gaza, about 60 km northwest of Jerusalem. The site consists of an ancient mound of approximately 3 ha (i.e., Tel Yafo) built on a kurkar sandstone ridge overlooking the Mediterranean Sea and during various periods also featured a sprawling lower city of as much as 6 ha. As an important site and port along the coast of the southern Levant, its occupation reflects nearly every major period from the Middle Bronze Age to the present, while the lower city experienced intermittent periods of substantial growth from the Hellenistic period onward.

The mound's stratigraphy became accessible following the abandonment of buildings in the center of the town during the British Mandate (1917–1947). The Ottoman period buildings on the upper part of the mound were destroyed or fell into ruins as a result of the British counter-insurgency in 1936 known as Operation Anchor (Fig. 1) (Gavish 2013). Consequently, the abandonment of structures on the mound of Tel Yafo permitted archaeological exploration, which began in 1948 under the auspices of the Israel Department of Antiquities and Museums and has continued to the present by various research institutions including the University of Leeds (1952), Tel Aviv University (1997, 1999), and the University of California, Los Angeles (UCLA), and Johannes-Gutenberg University in Mainz, under the auspices of the JCHP (since 2007) and in partnership with the Israel Antiquities Authority (IAA). Owing to antiquities legislation, salvage excavations have also been carried out since 1985 by the IAA (and more recently also by subcontracting Israeli universities) primarily along the mound's northern, eastern, and southern slopes in what is properly characterized as the lower city (e.g., Fantalkin 2005).

Taken together these excavations reveal a number of important discoveries connecting Jaffa's cultural heritage with that of the coastal plain, highlands to the east, and the Mediterranean basin as well as Europe. The earliest evidence for occupation at the site is dated to the late fourth millennium or the Early Bronze

Jaffa and the Jaffa Cultural Heritage Project, Fig. 1 Aerial photograph of the Jaffa's old city illustrating the effects of Operation Anchor, 1936. Note that the shape of the destroyed area on the mound (Tel Yafo) resembles an anchor

I (ca. 3500 to 3000 BCE), which consists of ceramic remains. It is possible that some of these ceramics are also indicative of the transition from the late Chalcolithic (Gophna 2002). During the Middle Bronze Age (ca. 1900 to 1530 BCE), the site was inhabited by a population characterized as Amorite, who constructed the site's first defenses, an earthen rampart crowned by a mudbrick wall. Following the transition to the Late Bronze Age, the site was inhabited by an Egyptian garrison from ca. 1460 to 1125 BC (Late Bronze IB to III, see Burke et al. 2017a). Textual evidence from Egypt is now amplified by Egyptian New Kingdom material culture including both imported and local Egyptian ceramics, epigraphic finds such as inscribed architectural fragments and scarabs, as well as other *aegyptiaca* (Burke and Lords 2010). The evidence for the Iron Age in Jaffa is piecemeal both on the mound and in the lower city, owing a great deal to the extensive and disruptive building efforts of the Persian Period. Nevertheless, a robust collection of ceramics from the Iron I, including Philistine bichrome, and successive phases of the Iron II (ca. 980 to 539 BCE), suggest a maritime port commensurate with the role mentioned for Jaffa in the narrative concerning king Solomon in the Hebrew Bible, notably, as an entrepôt to inland polities such as Judah and those in Transjordan. In contrast to the Iron Age remains, the Persian Period (ca. 539 to 332 BCE) in Jaffa is the first period during which both the mound and lower town were intensively occupied with nearly every excavation area yielding architectural remains from this period. These remains suggest, as at contemporary ports to the north, such as Dor, and to the south, such as Ashkelon, that the port played an important commercial role during the Persian Period, notably from the mid-fifth century when the city fell under Sidonian control (Burke 2011b).

Of comparable grandeur and physical extent, the remains of Hellenistic Jaffa reveal a cosmopolitan city caught in the struggle between Hasmonean rulers waging an insurgency against Seleucid rule during the second century BCE as evidenced in destruction levels of this period (Notley 2011). The Early Roman period saw Jaffa's importance as a port eclipsed by Herod's construction of major port facilities at Caesarea Maritima on the coast to the north of Jaffa. Nonetheless, the city persisted and even maintained a Jewish identity, which may have emerged during the Hellenistic period, if not earlier. This is suggested by, among other things, the remains of a Jewish patrician's home, which was

identified on the basis of the remains of Judean stone drinking vessels. Ample evidence of Jaffa's continuous and robust habitation during the Late Roman and Byzantine periods is present throughout Jaffa (Foran 2011).

During the early Islamic period, the site was a fortified coastal site and functioned as the port for the regional capital of Ramla located to its east. Fragmentary architectural remains as well as ceramics have been recovered predominantly from the lower town to the east, but also attested on the mound. During the Crusader period, ample ceramic remains reveal the interconnections of the city with various regions within the Mediterranean including Cyprus and Italy (Boas 2011; Burke 2011d). Evidence of the Crusader fortifications of the city can be found on both the northern and southern sides (Peilstöcker 2006). Following the Crusader period, the city experienced a low point in terms of size and archaeological evidence during the Mamluk period (Burke 2011e), after which the Ottoman period witnessed a lengthy period of rebuilding and expansion of the town to the east as it served as the principal port to European interests in the Holy Land (Kark 2011; Mirkin 2017).

The repeated themes in the historical legacy of Jaffa, which impinge upon its archaeological heritage, include its role as principal port to the central coast of Israel through the early twentieth century CE and the role that this port played as a zone of cultural interaction between Mediterranean cultures and those of the southern Levant. Whether through the residue of ceramics and artifacts left by the various ethnic groups inhabiting Jaffa or the institutions of pilgrimage established in the city, Jaffa was regarded as home to a wide range of ethnic groups from Amorites and Canaanites, and enclaves of Egyptians, Greeks, Jews, Arabs, Crusaders, Italians, Germans, and Armenians. Such a legacy therefore warrants a cultural heritage program that is able both to support and to integrate such diverse lines of research by leveraging its resources in an efficient manner under a shared framework for research as, for example, originally outlined by the Jaffa Cultural Heritage Project.

Definition

The Jaffa Cultural Heritage Project (JCHP) was founded in 2007 by codirectors Aaron A. Burke and Martin Peilstöcker to address the renewal of archaeological research of Jaffa and the stewardship of its archaeological heritage. The project's founding institutions include UCLA and the IAA. Additional members include Johannes-Gutenberg Universität, Mainz and the Old Jaffa Development Corporation (OJDC). From the project's outset, its directors outlined a fourfold program (Burke and Peilstöcker 2011) to address the needs of research (Peilstöcker 2011), publication (Peilstöcker and Burke 2011), presentation, and conservation (Strul 2011) of Jaffa's cultural heritage (Fig. 2). The project builds upon earlier efforts, especially the extensive archaeological excavations carried out by Jacob Kaplan (Burke 2011) whose work as the municipal archaeologist of Tel Aviv-Jaffa led to the development of the first plan for Jaffa's preservation (Fig. 3) against efforts to construct new buildings on the mound (Ajami 2011). The project also sought to integrate findings from unpublished excavations by a range of academic institutions including the University of Leeds (Isserlin 1950) and Tel Aviv University (Herzog 2008; Sweeney 2003), both of which carried out excavations in the second half of the twentieth century on Tel Yafo.

Key Issues/Current Debates/Future Directions/Examples

The challenges inherent to a cultural heritage research program such as the one outlined by the JCHP have materialized as both successes and substantive, material impediments. An early success of the JCHP's integrated design is evident in the recognition of the importance of the excavations conducted by Jacob Kaplan between 1955 and 1974 (Burke 2011c). A number of studies have emanated from this work (Burke and Lords 2010; Keimer 2011; Burke and Mandell 2011; Tsuf 2011; Burke et al. 2017a) as well as the renewal of excavations by the JCHP on Tel Yafo from 2008 to 2014 (Burke and

Jaffa and the Jaffa Cultural Heritage Project, Fig. 2 The JCHP's organizational framework

Peilstöcker 2017a). A central element of the effort is the project's integration of data via Geographic Information Systems (Pierce 2011), which permit not only the integration of plans from different excavations, but likewise data from a robust set of historical maps dating back to 1799 (Shacham 2011).

Data mining of European map and photo archives provides an indispensable source for understanding Jaffa's late Ottoman history (Shacham 2017), taken together with archaeological exploration in the lower town (Arbel and Rauchberger 2017; Aleksandrowicz and Giler 2017; Giler 2017). Such archaeology is elsewhere identified as Historical Archaeology, although it has, until late, not been practiced as such in Israel for remains dated from the sixteenth century CE on. Yet, now the remains in Jaffa's Qishle (Ottoman fortress), French Hospital, the Flea Market, and the Ganor Compound constitute some of the largest excavations of Ottoman remains in Israel.

As a testament the project's success in expanding the research methods employed in Jaffa, in 2014 the project initiated a survey of its premodern anchorages, as well as a geomorphological analysis of cores taken from the area of the lower city, under the direction of Shelley

Jaffa and the Jaffa Cultural Heritage Project, Fig. 3 Legally defined archaeological zones of preservation of Jaffa's heritage. Zone 1: the mound; Zone 2: buffer zone around tell; Zone 3: area of lower city during Ottoman towns that falls outside Zones 1 and 2

Wachsmann (Wachsmann 2014, 2015). These were intended to assist in the identification of the site's original port that is thought to have existed to the east of the mound (Burke et al. 2017b). These results were successful in identifying a brackish environment that was likely connected to the sea, possibly an estuary. A maritime survey was also begun off the coast through examination of suspect targets identified during an earlier multibeam survey. This led to the identification of a World War I ship that was torpedoed to the north of Jaffa (Wachsmann et al. 2014).

While the JCHP serves as a model for one approach to planning of a long-term, heritage-focused research project intended to meet the needs of both research and conservation, a number of issues pose considerable challenges to the continued success of this and similar projects (Burke and Peilstöcker 2017). In the first place, operating within an urban environment is exponentially more expensive than conducting archaeological and cultural heritage work in nonurban areas. For example, the sheer cost of conservation of architectural remains has meant that such elements of the original plan remain to be realized at a future point when funding, whether municipal or private, can be identified for this purpose. Similarly, the conservation work that has been done was infrequently undertaken in collaboration with the Jaffa Cultural Heritage Project's efforts, and consequently did not incorporate the project's collective knowledge of Jaffa's historical or archaeological heritage.

Related to this concern is the reality that development efforts by organizations such as the OJDC continue to place the desire for immediate

touristic development ahead of thoughtful deliberation about the stewardship of Jaffa's cultural heritage, although this cannot be properly considered until sufficient archaeological research has been completed and more importantly synthesized, as toward publication. A conservation survey still remains to be undertaken of the lower city in order to determine its conservation needs, which would then be followed by the drafting of a conservation plan and the pursuit of legal means for its enforcement. This is, however, being gradually addressed by the IAA, although its allocation of resources are far below those necessary to pre-empt the impact of rapid urban development efforts in this part of Jaffa. With the assistance of the local development company and municipal agencies, greater public presentation of Jaffa's historical, architectural, and archaeological heritage, however, has improved signage throughout the city, in which the JCHP has played an important role. The primary limitations faced in Jaffa remain universal challenges to cultural heritage projects with more than expeditionary research interests: sustainable funding, and municipal support and coordination.

Despite the many decades of archaeological research in Jaffa that preceded the foundation of the JCHP and the project's efforts to analyze and publish earlier investigations, the project has experienced continuous pressure to consider touristic development of its excavation areas in advance of its own renewal of exploration of these areas. Consequently, such attitudes toward the JCHP have resulted in a considerable appropriation of its resources by agencies ostensibly coordinating their efforts with the project, which has limited still further the available funding for archaeological research, conservation, and presentation of the site. Nonetheless, within the first 5 years of its existence, the project established itself as the de facto arbiter of Jaffa's archaeological heritage and its decade of work has resulted in more than five completed and in-preparation publication volumes, exponentially increasing the availability and visibility of publications addressing the site's history and archaeology.

Jameson, John H.

John H. Jameson
12,000 Year History Park, Cayce, SC, USA
International Committee on Interpretation and Presentation of Cultural Heritage Sites (ICIP), ICOMOS, Savannah, GA, USA
International Scientific Committee on Archaeological Heritage Management (ICAHM), ICOMOS, Washington, DC, USA

Basic Biographical Information

John H. Jameson is retired after 25 years with the US National Park Service. He currently is a Heritage Consultant with the 12,000 Year History Park on Congaree Creek, Cayce, South Carolina, United States.

Major Accomplishments

John Jameson's 30-plus years of public service encompassed a broad range of projects in cultural heritage management, preservation, and interpretation in several regions of the United States and overseas. At NPS, John has led important initiatives in public interpretation, education, and outreach. Beginning in the 1990s, he managed the Center's Public Interpretation Initiative, a long-term outreach program, international in scope, that involved numerous government-sponsored symposia, training workshops, seminars, exhibits planning and development, website development, and publications on the topic of public education and interpretation of cultural heritage. A recognized national leader in public archaeology programs, he has been a key player in the organization and development of training courses for park rangers and cultural heritage specialists in the effective interpretation of archaeological and cultural heritage resources. As NPS curriculum coordinator and Interpretive Development Program (IDP) certifier, he evaluated professional interpretation and education programs in the National Park Service. In the

late 1990s, he organized and coordinated an interdisciplinary task group in developing the Archeology Interpretation Training Module (NPS IDP Module 440). He has extensive international experience, including invited critiques of heritage interpretation programs in the United Kingdom, Ireland, Australia, Canada, China, Poland, and Ukraine. In November 2005, he received the coveted Sequoia Award for significant, long-term contributions to interpretation, education, and partnerships in the US National Park Service. He has served as member and chair of numerous professional society committees and is frequently a keynote and plenary speaker at international conferences. From 2006 to 2015, he served as founding member and vice president of methodology and policy, International Committee on Interpretation and Presentation of Cultural Heritage Sites (ICIP), and ICOMOS.

Internationally, John has served (2006–2015) as vice president of the International Committee on Interpretation and Presentation (ICIP), promoting international dialogue and civic engagement. These efforts include the organization of symposia, seminars, and workshops on internationally relevant interpretation principles in Peru, Ireland, the United Kingdom, the United States, Ukraine, Jordan, Spain, Portugal, and Turkey. He continues to work with cultural heritage specialists and community members in recognizing the essential role of community involvement in explaining the relevancy and value of cultural heritage in everyday lives of people.

From 2008 to 2013, John served as advisor to the director of the Ancient City of Tauric Chersonese and its Chora World Heritage Site (aka National Preserve of Tauric Chersonesos) (https://whc.unesco.org/en/list/1411/) in Crimea, Ukraine, including coordinating a seminar at the site on archaeology and cultural heritage interpretation principles and tourism challenges.

Since January 2014, he has functioned as Staff Secretary and Heritage Consultant for the 12,000 Year History Park Working Group. During January to June 2014, as a consultant with River Alliance, he helped to establish the 12,000 Year History Park Working Group. During this time, he played a major role in the drafting of a Long-Range Interpretive Plan, the signing of an MOU among Core Partners (City of Cayce, the River Alliance, and the US National Park Service), and the adoption of a city archaeological ordinance. In 2015, John led efforts to develop a program of volunteer-led tours in conjunction with "Burning of Columbia" Civil War 150th Sesquicentennial Commemorations. Additional programs since 2015 have involved the development of interpretive theme modules on topics such as Civil War Human Interest Stories, Fort Congaree and the 18th Century Deerskin Trade, Native American Lifeways, and Nature in the Park. His latest projects include project manager of a National Park Service American Battlefield Protection Program grant to create a Preservation Plan for the 12,000 Year History Park's Civil War earthworks and as chief organizer of a city-sponsored seminar on the nature and historical significance of the "The Congarees" as an economic and military center of activity in eighteenth-century South Carolina.

John has edited and contributed to several seminal works on cultural heritage management and interpretation. He currently serves on the Editorial Board of the European Journal of Archaeology and as Assistant Editor of the Journal for Community Archaeology and Heritage. His publications include *Presenting Archaeology to the Public: Digging for Truths* (AltaMira,1997); *Ancient Muses: Archaeology and the Arts* (University of Alabama Press, 2003); *The Reconstructed Past: Reconstructions in the Public Interpretation of Archaeology and History* (AltaMira, 2004); *Unlocking the Past: Celebrating Historical Archaeology in North America* (UPF, 2005); *Past Meets Present: Archaeologists Partnering with Museum Curators, Teachers and Community Groups* (Springer, 2007); *Out of the Blue: Public Interpretation of Maritime Cultural Resources* (Springer, 2007); *The Heritage Reader* (Routledge, 2008); *Training and Practice for Modern Day Archaeologists* (Springer, 2013); and *Transforming Heritage Practice in the 21st Century: Contributions from Community Archaeology* (Springer, 2019).

Japan: Cultural Heritage Management

Akira Matsuda
School of Art History and World Art Studies, University of East Anglia, Norwich, UK

Introduction

"Cultural heritage" (*bunka isan*) is a relatively new term and concept in Japan. It became popular only after Japan's accession to UNESCO's Convention Concerning the Protection of the World Cultural and Natural Heritage in 1992. Prior to that, the term "cultural property" (*bunkazai*) was predominantly used in both official and everyday language. Today, the two terms are used almost interchangeably, and while "cultural heritage" is increasingly in use, especially in relation to World Heritage, "cultural property" is still prevalent and more familiar to most Japanese people.

It is important to note that cultural property in Japan is legally and officially defined. On the national level, the Law for the Protection of Cultural Properties (*Bunkazai Hogohô*) generally defines eight categories of cultural properties (see below). The designation of cultural properties of national importance is made with reference to this law. In addition, all prefectures and most municipalities have laws that build on the Law for the Protection of Cultural Properties, and according to them cultural properties of prefectural and municipal importance are defined and officially designated. Cultural properties are thus made *from above* by the government, be it national or local. This can be contrasted with cultural heritage, which, as many critics have convincingly argued (Lowenthal 1998; Howard 2003: Chap. 6; Graham and Howard 2008), is essentially made through people's identification with it and as such does not necessarily require legal and official designation.

That cultural property precedes cultural heritage both as a term and a concept can explain why "Cultural Heritage Management" in Japan is often understood as the management of legally defined cultural properties. In this sense, Cultural Heritage Management in Japan is strongly characterized by its legal and official nature.

Definition

Legal and Official Definition of Cultural Properties in Japan

Although in English-speaking countries "Cultural Heritage Management" – or CHM – is sometimes equated with the management of archaeological resources, the extent of cultural heritage is clearly far greater than that of archaeology. This is particularly the case in Japan, where intangible aspects of culture have long been considered and officially recognized as cultural properties. Considering this, it is useful to briefly summarize what is defined as cultural properties in Japan, before focusing on the management of archaeological resources.

The Law for the Protection of Cultural Properties regulates all aspects of the nation-level

management of cultural properties in Japan (Agency for Cultural Agency 2007, 2010). It generally defines eight categories of cultural properties: (1) tangible cultural properties, (2) intangible cultural properties, (3) folk cultural properties, (4) monuments, (5) cultural landscapes, (6) groups of traditional buildings, (7) buried cultural properties, and (8) conservation techniques for cultural properties (Clauses 2, 92, and 147). Archaeological resources are mostly concerned with "buried cultural properties (*maizô bunkazai*)", which in practice apply to archaeological materials buried in the ground. In addition, excavated archaeological objects that have significant value may be designated as "important cultural properties" or "national treasures" under the category of "tangible cultural properties", and excavated archaeological sites that have significant value may be designated as "historic sites" or "special historic sites" under the category of "monuments."

Key Issues

The Management of Buried Cultural Properties

There are approximately 460,000 registered archaeological sites (legally called as "areas containing buried cultural properties") in Japan. The Law for the Protection of Cultural Properties requires that those who propose an investigative excavation or development work on a known archaeological site notify the commissioner of the Agency for Cultural Affairs in advance. After receiving the notification, the commissioner can instruct the excavator/developer on necessary measures to take for the protection of the site. If the proposed development work is considered to inevitably destroy the site, "rescue excavation" is implemented to archaeologically record finds from it before destruction – this practice is called "preservation by record" (*kiroku hozon*). Objects retrieved from rescue excavation must be given to police unless their owner is identified. Judgment is then made as to whether they are officially recognized as cultural properties. If the objects are indeed recognized as cultural properties and if they still remain ownerless, they then become property of the prefecture in which they were discovered.

It is conventionally accepted that the costs of rescue excavation before construction of a private home for non-profit purposes are to be borne by the local and/or national government. When rescue excavation takes place prior to development work for any other purposes, its costs are to be paid by the "polluter," namely, the developer, be it a public or private body. These costs include the expenses for excavating the site, processing the finds, and publishing the excavation report. The Law for the Protection of Cultural Properties does not clearly stipulate the principle of "the polluter pays" (Tanaka 1984: 84); its clause 93–2 only states that when there is a "particular need" to protect the buried cultural properties that are going to be affected by development works, the commissioner of the Agency for Cultural Affairs can specify "necessary measures to be taken." It is generally accepted that these "measures" include asking the developer to pay the expenses of rescue excavations. However, there is no specific obligation for the developer to pay those expenses, as the "measures" constitute merely administrative direction. This issue, recurrently raised by developers, is one of the major problems in the Law for Protection of Cultural Properties.

In the fiscal year 2010, 35,467 proposals were made for construction works to be implemented in areas containing registered archaeological sites. These proposals resulted in 7,951 rescue excavations (Hayashi 2011: 50). Meanwhile, 428 research excavations were undertaken in the fiscal year 2009 (Hayashi 2011, Fig. 2). From these figures one can infer that approximately 95% of all archaeological excavations in Japan are carried out in the sector of rescue archaeology, where 5,963 archaeologists – officially referred to as "specialists in charge of buried cultural properties" (*maizo bunkazai tantou senmon shokuin*) – work today (Hayashi 2011: 47).

The nationwide management system for buried cultural properties developed rapidly from the mid-1960s onward (Agency for Cultural Affairs 2001: 263), reflecting the fast growth of the nation's economy and the concomitant increase of development work across the country. From the

1960s, archaeologists working at the boards of educations (*kyôiku înkai*) of local governments became in charge of rescue excavations. In 1965, there were only eight experienced field archaeologists employed in boards of education, but this number rose to 35 by 1968 (Tsuboi 1992: 3). As archaeologists were increasingly employed and positioned at local governments all over the country, a nationwide administrative system for managing buried cultural properties was gradually established, first at prefectural and then municipal levels, under the national government's supervision. Some local governments set up "semipublic" self-governing foundations specializing in archaeological investigation. This was driven by economic considerations – the foundations could ask the developers to pay for the costs of rescue excavations including the salaries of archaeologists, and thus the local governments could avoid the financial burden of hiring archaeologists as direct employees (Tanaka 1984: 83).

As Japan's economy continued to expand rapidly, the number of rescue excavations increased exponentially from the 1970s to the mid-1990s. The great majority of these excavations were funded by the developers, and the employment of archaeologists at local governments and semipublic archaeological foundations increased accordingly. Some prefectures, municipalities, and foundations established within themselves "centers for buried cultural properties", which took charge of excavation, analysis and storage of archaeological finds, and dissemination of archaeological knowledge and information in a systematic manner (Tsuboi 1992: 10; Agency for Cultural Affairs 2001: 272–273).

Thanks to the stable operation of the nationwide management system for buried cultural properties, the number of archaeological sites destroyed without being investigated and recorded before development work has decreased considerably. It is worth remembering, however, that the recorded sites have rarely been preserved after the termination of rescue excavation (Tsuboi 1992: 5). Archaeologists working in the sector of rescue archaeology hardly broach the subject of site preservation in situ, because of their entire, or at best partial, dependence on the developer to fund rescue excavations. Only archaeological sites of significant historical or scientific importance are physically preserved through the amendment of development plans or their designation as "historic sites" – the latter often requires purchase of the land by the national or local government (Tanaka 1984: 83; Tsuboi 1992: 5–8). Except for these rare cases, the majority of sites are preserved only "by record" and thus transformed into over 2,000 excavation reports annually (Agency for Cultural Affairs 2001: 284).

Archaeologists working at the boards of education and semipublic archaeological foundations are not only in charge of the implementation of rescue excavations but also the protection and restoration of archaeological sites in each prefecture or municipality, as well as the dissemination and publication of information gained from archaeological investigations for educational purposes. One of the popular educational activities that they organize is *gensetsu*, an abbreviation of *genchi setsumekai*, which literally means "explanation meeting on the site." *Gensetsu* aims to present the results of the excavation to the public at the site. *Gensetsu* was first held in 1956 at the excavation of Asuka Temple in Nara, and has been widespread throughout the country since the mid-1970s (Agency for Cultural Affairs 2001: 290). Today, *gensetsu*, usually held on weekends, are announced in newspapers and on television prior to the selected date and sometimes draw thousands of visitors (Okamura 2000: 62).

Current Debates

Current Challenges to the Management System for Buried Cultural Properties

The current management system for buried cultural properties is faced with two major challenges: the effect of the nation's long-term economic crisis and the pressure for the privatization of rescue archaeology (Okamura and Matsuda 2010: 104–106). In the second half of the 1990s, Japan began suffering from a long economic downturn, which led to the considerable reduction of development work all over the country. The decrease of development work itself

should probably be welcomed, as it implies fewer rescue excavations and, hence, less destruction of archaeological sites. However, the situation is far more complex in reality because the current system for buried cultural properties functions on the basis of certain supposed amounts of development work.

The amount of money spent for rescue excavations was 132 billion yen at its peak in 1997, and it diminished to 69 billion yen by 2010 (Hayashi 2011, Fig. 3). Effects of this can already be seen in the number of archaeologists employed at local governments and semipublic archaeological foundations: it hit its peak at 7,111 in the fiscal year 2000 and dropped to 5,963 in the fiscal year 2010 (Hayashi 2011, Fig. 1). The decrease of archaeologists working in the sector of rescue archaeology suggests that the management system for buried cultural properties in Japan has heavily relied on the nation's healthy economy. Hit strongly by the Great East Japan earthquake and tsunami in 2011, Japan's economy is likely to remain stagnant for another several years, if not longer. While it is still unclear how exactly this will affect the management system of buried cultural properties in the long term, it is likely that the emphasis that the system has placed on the protection and preservation of buried cultural properties will gradually move to their utilization, in particular so they can generate some income for local communities.

The pressure for the privatization of rescue archaeology poses another big challenge to the current management system for buried cultural properties. Private archaeological units have already been in operation for a few decades, particularly in the Kanto region, but most of them were small in size and led by professional archaeologists. In contrast, newly emergent private units are established at the initiative of, and within, construction companies, and today they are growing fast and increasingly demanding for the privatization of rescue archaeology. For these construction companies – private developers – rescue archaeology offers a new attractive business market, especially because they need to counteract the effect of the recent recession in the construction industry. Some fear that the marriage between private developers and private archaeological units might lead to the poorer quality of rescue excavations, while others are more optimistic. Currently, debates are going on as to how to ensure the quality of rescue excavations.

Japan: Cultural Heritage Management Education

Katsuyuki Okamura
Higashi-Yodogawa Research Centre, Osaka City Cultural Properties Association, Osaka, Japan

Introduction and Definition

In Japan, the term "cultural heritage" is becoming better known due, in part, to a rise in interest in World Heritage Sites among travel enthusiasts initiated by a popular TV program just after the Japanese government signed the Convention Concerning the Protection of the World Cultural and Natural Heritage in 1992. However, the term is not used to refer to domestic "heritage" sites, and has not yet taken the place of the traditional term, "cultural properties."

Cultural properties or heritage in Japan is managed by various organizations. Though museums have played a central role in its promotion, a number of educational activities are also conducted by archaeological units.

At present, Japan, a country inhabited by 128 million people, has over 440,000 registered archaeological sites. The number of rescue excavations in Japan increased exponentially from the 1970s to the mid-1990s, reflecting the rapid growth of the nation's economy over that period. Today, despite a recession, approximately 7,000 rescue excavations are carried out yearly across the country, and account for approximately 95% of all archaeological excavations in Japan. As of 2008, the total number of field archaeologists was 6,255 and all 47 of Japan's prefectural governments and over 65% of municipal governments (1,192 out of 1,834) have cultural properties sections. This high ratio of active units of field specialists clearly indicates the importance of maintaining CHM across Japan.

Key Issues

Preservation and Use of Cultural Properties

As the current CHM system in Japan was established at and developed by regional boards of education under the national government's supervision, archaeologists working at these public sectors are generally involved in a variety of educational activities; not solely archaeological, but sometimes architectural and other tasks related to heritage. All these activities are carried out under the title of bunka-zai no hozon to katsuyo (Preservation and use of cultural properties). This is an official policy and is also used as an administrative maxim for CHM in Japan. A good example of such activities in archaeology are the open days (genchisetsumeikai, or simply gensetsu: public site explanation), during which the results of the excavation are presented to the public at the site. Gensetsu, usually held on weekends, are announced in newspapers and on television prior to the selected date. Sometimes gensetsu draw thousands of visitors, not only archaeological enthusiasts but also local lay people. In addition to gensetsu, public lectures and symposia on archaeological subjects are frequently held, and interested people can read reports on recent archaeological discoveries or listen to professional archaeologists.

Some prefectures, municipalities, and foundations have even established "centers for buried cultural properties," which are in charge of the excavation, analysis, and storage of archaeological finds, and the dissemination of archaeological knowledge and information in a systematic manner.

Heritage Studies in School and Higher Education

As a part of elementary school curricula, students at the age of 12 are expected to go to museum to study local history and archaeological sites in order to appreciate cultural heritage. Local cultural heritage is sometimes used for off-school activities or as an integrated learning program for years 10–12. For instance, every year the Osaka Museum of History conducts an outreach program with elementary schools in Osaka City to excavate the Naniwa Palace site. This kind of hands-on activity is becoming popular in heritage education across the country. In junior and senior high school curricula, the subject most usually linked with cultural heritage is history.

In higher education, Nara University first set up its Department of Cultural Properties in 1979, which integrated studies on cultural heritage to train heritage managers and conservators, and to meet the then urgent demand of researchers for rescue excavation. Kyoto Tachibana University also set up a Department of Cultural Properties in 1997 which will be converted into the Department of Historical Heritage in 2012. The number of universities with departments or courses entitled "cultural properties" or "cultural heritage," including "World Heritage," has been increasing recently and now totals over 20.

A recent interest in archaeological qualification has remodeled educational programs at some universities. Issues surrounding qualifications had been discussed in the past, but development did not take place until late 2000 after the "Japan Association for Preservation of Cultural Properties," consisting of 76 private companies for excavation, air survey, analysis, conservation and others, initiated its own qualification examination in 2007. The National Agency for Cultural Affairs (Bunkacho) started investigating the need for excavation qualifications in 2008 and the Japanese Accreditation Board for Archaeological Researchers was founded in 2009. Presently, Waseda University and other eight universities are offering educational programs to enable students to become qualified as an "archaeological researcher" by the Board. More universities may join this movement in the future, as "qualification" generally attracts students.

Museum curatorial qualification can be gained at 344 universities (April, 2009) and this system will be intensified from 2012 to help further develop curatorial skills and knowledge. However museum positions are quite limited and, for example, in 2007 only 61 out of 10,427 qualification holders could were able to find a job in a museum.

As for professional training for heritage managers at local governments, every year the Nara National Research Institute for Cultural Properties offers a variety of courses to develop knowledge and skills for cultural heritage. For instance, in 2011, there are 14 courses covering a wide range of topics including research method for architectural features, stone artifacts handling, building conservation and restoration, scientific chronology, conservation science (metal and wooden objects), environmental research, survey mapping, recording and GIS, photography, site report, and site management.

Future Directions

Firstly, there are a small number of experts who specialize in heritage studies, management, and education in comparison to the demand for their teaching. Secondly, there is poor exchange of information between teachers, and heritage managers and archaeologists. Finally, since information on educational activities and curriculum for CHM is divided between a number of organizations such as local authorities, museums, and archaeological units among others, and has not been organized in a systematic manner, it is difficult to grasp the overall outline and to access the right information.

A national storehouse is need for the exchange of information about programs and curriculum development, and for education in archaeology.

Japan: Field Archaeology

Yumiko Nakanishi
Cultural Properties Protection Division,
Osaka Prefectural Government,
Osaka, Japan

Brief Definition of the Topic

Principles

The basis for archaeological intervention in Japan is the *Law for the Protection of Cultural Properties* inaugurated in 1950 and updated regularly since. Archaeological resources underground are registered as "buried cultural properties (*Maizou Bunkazai*)." Since then every excavation has to be notified to the responsible government department, traditionally the Board of Education. Most archaeological fieldwork takes the form of *rescue excavation* (CRM) in advance of development rather than research projects. Universities do undertake excavations for academic purposes, but these are overwhelmingly exceeded by rescue work, both in number and budget. Academics are required to obtain permission to excavate from the local authority (who may not give it).

On the principle that it is better for buried cultural properties to be preserved underground than to be destroyed, the initiator of the development is required to pay for excavation of archaeological deposits in advance of their destruction. This principle was challenged in the courts in the late 1970s and the early 1980s, when private development companies sued for the losses caused by covering these costs. But the High Court of Tokyo found in favor of government and ruled that developers should cover the cost of excavation but with the condition that there should be the limit defined by an "appropriate level of investigation." Not all remains of the past are eligible for record: according to government advice dated 1998, only remains dating back to the Middle Ages and earlier are mandatorily subject to investigation, but those particularly significant to the local history are exceptionally treated.

Methods

Nondestructive field methods may be used at the evaluation stage, although rescue archaeology mostly uses *test pits* to determine and estimate the depth of cultural layers, as well as the anticipated structures and their likely date. This information also allows an estimation of the cost and duration of the intervention, which is then fed into the *project design*. The project design forms the basis for negotiation with the developers. Once fixed, archaeological contractors tender for the work, comprising the necessary equipment and the required labor force. Payment is usually calculated according to the volume of soil to be removed or the numbers of workdays required.

A mechanical excavator ("jumbo") is used to remove top layers and then digging switches to human labor using hoes and the other tools. Narrow trenches are first dug at the edges of

Japan: Field Archaeology, Fig. 1 Excavations in progress in Nara, 2012. Tools in use. (By courtesy of Nara National Research Institute for Cultural Properties)

the area to be excavated to reveal sections through the deposit. These trenches provide drainage, and their sections are used as a guide to the excavators, who peel back from them, layer by layer. Excavators use a versatile trowel hoe on a long handle, which can pick, cut, slice, and create a smooth surface (Fig. 1). The spoil is removed using electrically driven belt conveyors. When the surface of the layer is clean, those features showing in it are recorded by photography and drawing. Features and collected artifacts are located in three dimensions using a grid system connected to the national and world geodesic systems. A new departure is the recording of excavations using overhead photography from a helicopter or a crane supporting a cage. The photographs are used to generate measured drawings, which are then checked on site.

Once excavations are complete, all artifacts will be washed and marked with a serial number to identify date and location of discovery. Broken pieces are refitted, drawn, and photographed. This is often done by part-time workers. Comprehensive excavation reports are prepared containing all the information collected during the excavation. The public are invited to view the excavations' open days. This usually includes a safe route overlooking the excavated and a

Japan: Field Archaeology, Fig. 2 Excavations in progress: use of conveyor. (By courtesy of Nara National Research Institute for Cultural Properties)

few tents, one for reception and others for exhibiting artifacts (Fig. 2).

Archaeological work in advance of development is big business. A recent example of a large-scale urban project is the Second Keihan Highway project, which involved a national expressway and a bypass about 27 km in length. The section crossing Osaka was about 16.1 km and had 18 potential sites ("areas known to contain cultural properties"). Agreement for trial excavations was negotiated between the different agencies and authorization given to the contractor, in this case the Osaka Center for Cultural Heritage (OCCH), a nonprofit foundation partly invested by Osaka Prefectural Government. After completing trial excavations in 1996, the area in need of excavation was estimated as about 450,000 m^2. In 2000, the full-scale excavations started at Tsudajo site in Hirakata City, and all excavations were completed in January 2010.

Reflections

Privatized contract work needs appropriate surveillance, or it can simply become "the cheapest option." This must be avoided: to record sites properly requires the application of a certain standard, for example, by the issue of licenses, which has been under discussion for the past few years. A second concern is the usage of the new knowledge that is being generated. Many reports are not well researched nor accessible to the public. Some have been kept long in the archive without ever being consulted. We also need to rethink the role of archaeologists in the public sector. It is probably a good moment to discuss opening up field archaeology in Japan to wider involvement.

Japan: Indigenous Occupation

Naoko Matsumoto
Okayama University, Okayama, Japan

Introduction

Ainu people and culture have been marginalized in the colonial politics of Japan. Their existence as an Indigenous people was denied over a long period, and many Japanese remain ignorant about this ethnic group (Weiner 1997). On the other hand, the Ainu people gathered much attention as direct descendants of the Indigenous inhabitants of the Japanese Archipelago, who were pushed off to the north by the agricultural ancestors of current Japanese since the Yayoi period. Early investigators proposed a Caucasian ancestry as the origin of Ainu, but this theory was rejected by later anthropological studies.

It has often been assumed that the Ainu people are direct descendants of the Jomon people, but the relationship between the Ainu and the Indigenous population of Japan is not so simple. Recent genetic analysis has confirmed that the Ainu people in Hokkaido and the native Okinawan people share similar characteristics in spite of their geographic distance (Japanese Archipelago Human Population Genetics Consortium 2012). This supports the hypothesis that the Ainu and Okinawan people descended from the Indigenous population of Jomon period, Japan, with little genetic influence from the immigrants who came to Japan from the continent in and after the Yayoi period.

Ainu place names remain in the northern part of Honshu, the main island of Japan, indicating that the Ainu-speaking people once lived there before retreating to Hokkaido. Archaeological evidence and historic documents of the Ainu are scarce before documents in the fifteenth century. However, the Ainu culture seems to have developed from the Satsumon Culture (seventh to thirteenth century CE) with an influence from the Okhotsk Culture (Sato et al. 2007).

Definition

The Ainu are an Indigenous people who inhabit the northern part of the Japanese Archipelago. Official estimates of the population are around 25,000 based on the 2006 census in Hokkaido, while the unofficial number is estimated at up to 200,000 (Poisson 2002). Ainu languages were spoken by Ainu people in Hokkaido as well as in the southern half of the island of Sakhalin and the Kuril (Chishima) Islands, but only the Hokkaido variant survives today.

Key Issues

The subsistence diet of the Ainu people was based on fishing, hunting, and gathering, as well as the cultivation of wheat, millet, buckwheat, and beans. They obtained rice and metal through trading with Japanese in the south. However, their relationships with the Japanese became increasingly fraught and resulted in a series of battles between the Ainu and the Japanese: the Battle of Kosyamain in 1457, the Battle of Syaksyain in 1669, and the Battle of Kunashiri-Menashi in 1789. The Ainu was defeated in each of these battles, and fell completely under the control of the Japanese after the Battle of Kunashiri-Menashi.

The traditional religion of the Ainu is animism, in which everything in nature is believed to have a *kamuy* (spirit or god) on the inside (Honda 1993). The bear is considered to be very special in the Ainu worldview. Ceremonies for sending back the spirits of bears is a well-known Ainu tradition called *Iomante*.

There is no particular reservation for the Ainu. Many Ainu people live in Nibutani, Biratori Town, Hokkado. The place name "Nibutani" is derived from the Ainu word "Niputai," meaning the wooded place. Dr. Neil Gordon Munro, a prominent researcher of the Ainu, opened a doctor's office in Nibutani in 1930 and had taken care of many patients for free until his death in 1942. Shigeru Kayano, who became the first Ainu member of the Diet in 1994, was from Nibutani.

Current Debates

The Ainu people have suffered under discriminatory policies and forced assimilation for more than a century since the Meiji restoration (1868) when the Japanese government included Ezo as part of Japan and changed the name to Hokkaido. At this time, the Ainu people were registered in the Japanese census and were compelled to use Japanese last names. Their language and cultural practices were prohibited. In 1875, Japan and Russia signed the Treaty of St. Petersburg based on the proposal that Russia should control Sakhalin and Japan would claim the Kuril Islands (Okada 2012). The Ainu people had to choose their citizenship, and some of them were forced to leave the homeland.

The Law for the promotion of Ainu Culture and the Dissemination and Advocacy of Knowledge in Respect to Ainu Traditions (Ainu bunka shinko-ho) was passed in 1997. Until this time, the government stated there were no ethnic minority groups in Japan. In 2008, the Japanese government finally recognized the Ainu as Indigenous people of Japan.

Because of such long-term political oppression, many Ainu people have tried to hide their ethnic backgrounds and/or to marry Japanese to lessen the chances of discrimination against their offspring. As a result, many Ainu are indistinguishable from their Japanese neighbors today and the Ainu language is moribund. The number of "pure" Ainu was recorded as 300 in 1966.

Today, however, there are a number of people who are interested in traditional Ainu culture and trying to revive Ainu culture and language. Oki Kanō is an Ainu Japanese musician who plays *tonkori*, an Ainu stringed instrument and performs traditional Ainu music and other styles of world music. There are some Ainu *kotan*, meaning Ainu village, in Hokkaido as tourist sites. The largest of such *kotan* is near the hot springs resort area at Akanko. Interactions between the Ainu and other Indigenous peoples in the world have also become much more frequent.

Japan: World Heritage

Yu Song
Department of Recreation, Sport and Tourism, University of Illinois at Urbana-Champaign, Champaign, IL, USA

Introduction

Until 2010, Japan has 11 cultural heritage site inscribed on the World Heritage List. Considering that Japan accepted the World Heritage Convention since 1992, the process of identification, nomination, and inscription of World Heritage Site is quite speedy. A close examination of those sites allows the observation that each site can be seen as a case study presenting one or several issues that deserve an in-depth analysis. In the following discussions, I will elaborate these cases on the issues of cultural and spiritual values, tourism and impact of tourism, interpretation and political contestation, modernization, commercialization and authenticity, indigenous community, etc. A brief examination of the heritage laws and regulations of Japan follows, and finally a general discussion sums up this entry.

Examples

Buddhist Monuments in the Horyu-ji Area

Horyu-ji Area is located at Nara, the place where Japan claimed as the terminus of Silk Road. Since 206 BCE, Silk Road became an important trade route for traders, merchants, pilgrims, missionaries, nomads, and soldiers from Ancient China, crossing the Ancient India, Ancient Tibet, and Persia to Mediterranean countries for about 3,000 years. The extensive interconnected network gradually evolves to be a cultural communication channel that greatly accelerated transmission and convergence of different cultures. The World Heritage Site Buddhist Monuments in the Horyu-ji Area well manifested the application of new religion Buddhism and advanced wooden architecture construction technologies imported from China. However, with the purpose of de-emphasizing Japan culture as an affiliate of Chinese culture, the official website of Osaka and Nara stresses the cultural influence of Europe and North Africa and accentuate the distinctive style of Japanese architecture (Osaka and Nara 2010).

With the arrival of Buddhism, Nara flourished. Between 710 and 784, capital city of Japan – Heijokyo – became the center of Japanese cultural with numerous number of buildings, books, and assets settled in Nara and passed down to today. Nara has the largest number of buildings designated as National Treasures in Japan. Although

with abundance of cultural tourism resource, Nara is overshadowed by its more famous neighbor Kyoto. For time-pressed group travelers, Nara is often omitted on the itinerary.

Buddhist Monuments in the Horyu-ji Area are known as the world's oldest wooden building structures in the world; however, few tourists know that all the buildings have been rebuilt, reconstructed, or remodeled in historical times except the Hoki-ji temple. This issue raised the question of how to determine an authentic wooden building structure in terms of preserving the values authentic to its history.

Gusuku Sites and Related Properties of the Kingdom of Ryukyu

The site is located in Ryukyuan Okinawa, a chain of islands that are detached from the mainland Japan and present a considerably different culture formulated during Ryukyuan Dynasty (the twelfth to seventeenth century). Before being invaded in 1609, Ryukyu Kingdom was a tributary state of imperial China. In Ming and Qing Dynasties (the seventeenth to nineteenth century), the political power in Okinawa still paid tribute to the Chinese emperor (Baidu 2010). From the late nineteenth century, Ryukyu Okinawa became a target of territory dispute between China and Japan. During this historical period, China suffered from internal corruption and colonial occupation and was too weak to send soldiers to a remote island; instead it made diplomatic objections and asked former United States President Ulysses S. Grant to arbitrate. Grant stood behind Japan and allowed Japan to rule the islands in their favor. The superpowers paid no attention to indigenous islanders. From the beginning of the twentieth century, compulsory Japanese education was enforced on the Ryukyu children, whereby they were taught Japanese language, culture, and identity. The use of their native language was strictly forbidden. Military activity on the island, before and during World War II, had a devastating effect on Okinawan people and their cultural heritage. After World War II, under the San Francisco Peace Treaty, US military controlled over Okinawa from 1945 to the year 1973, when sovereignty was given back to Japan. China signed the Potsdam Declaration in 1945, which claims that Ryukyuan Okinawa should be given back to China, but with the eruption of inner war during 1945–1949, China never really puts it power on Ryukyuan Okinawa.

The territory dispute never ended. In 2010, Japan seized a Chinese fishing boat and once again intensified dispute that has lasted for several centuries (TVNZ 2010). There are also reports about the protesting activity of indigenous, showing their anger towards Japanese political sovereignty especially on the issue of allowing so many American soldiers to be stationed on the islands instead of the mainland, and call for the independence of their land (Baidu).

With all of the above observations of the historical problems associated with Ryukyuan Okinawa, it is interesting to look into Gusuku sites and related properties as embodied manifestation of Kingdom of Ryukyu (the twelfth to seventeenth century), which exists in a time period that is relatively independent of other political powers. The site presents a complex social structure of disappeared Ryukyu Kingdom in the form of ruins of castles, fortresses around the settlement, and the sacred tombs. Although these building structures present a mixture of many influential cultures, they still reserved their cultural uniqueness that can only be found in Ryukyuan Okinawa. None of the Japanese travel website, both official and nonofficial, mentions a word about the turbulent history of this particular site and erased the information about the damage of site caused by World War II and restoration in recent decades.

Another fascinating observation is that the most important castles in the site – Shuri Castle – was reconstructed in 1992. The reconstructed gigantic mansion is featured by colorful ceilings and pillars, while the other four castles inscribed are ruins with only brick walls and groundwork left by wars. The Shuri Castle looks quite isolated and awkward in a complex of ruined monuments and sites. It is apparent that Japanese government wanted to de-emphasize the history of Ryukyuan Okinawa, especially the memories associated with the World War II.

Himeji-jo

Himeji-jo is the early seventeenth-century Japanese castle comprising of 84 buildings with highly

developed defense system and protection device. Dating back to 1500s, the Himeji-jo is the biggest castle in all of Asia. With the wooden walls stocked with fireproof white plaster, unwelcomed visitors will be attached by firing guns and shooting arrows and also for pouring boiling water or oil (World Heritage Site Organization 2010).

Himeji-jo is an exemplar of an age of militarism, an important principal of expansionism. I consider that the expansionism – the desire to maintain a strong military capability – and aggressively invading other countries for the country's own national interest are the main reason for the eruption of WWII and should be mentioned and warned to the domestic and international visitors. From the online resources, there is no evidence of the availability of such information.

The site can be easily accessed by train or bus. From Tokyo, one Nozomi train per hour runs through to Himeji, and it takes about 3 h to get visitors to the site. For this reason, the site is extremely crowded in cherry blossom season when the grounds are full of blooms. Some popular travel-guiding websites suggest the international visitors to peak season to avoid the domestic visitors' flow.

Hiroshima Peace Memorial (Genbaku Dome)

The Atomic Bomb Dome is a skeletal-domed building in Hiroshima City which still stands to commemorate the dropping of the atomic bomb. The atomic bomb, dropped for the first time in history, exploded some 580 m above Hiroshima City. The only survival built structure – Genbaku Dome – was intentionally preserved immediately after bombing and eventually became famous symbol of the bombed city. ICOMOS site in danger 2006/2007 addressed the issues surrounding the proposed high-rise building near the dome, in the UNESCO world heritage buffer zone. The case triggers the thought about the integrity of heritage and the threat of modernity on the memory of ruthless war.

Take a closer look at the site, it can be easily recognized that the official guidebooks and the online site museum focus on historical fact and the suffering of Japanese people after war, with no comments about the role of Japan in World War II and any information about the miseries the countries invaded by Japan (The Outline of the Hiroshima Peace Memorial Museum 2010). By positioning Japan as a victim, both domestic and international tourists are misled by a one-sided picture of World War II and the dropping of atomic bomb in Hiroshima. This can potentially decrease the value of Hiroshima Peace Memorial as a place for people to look retrospectively at the war in the history and pray for peace in the future.

Historic Monuments of Ancient Kyoto (Kyoto, Uji, and Otsu Cities) and Historic Monuments of Ancient Nara

The two sites are both ancient capital cities in Japan and designated as the UNESCO World Heritage Site with similar reasons. However, as formerly discussed, Nara is shadowed by Kyoto and received less visitation.

Kyoto is nestled in the mountains of Western Honshu. Designed as a scaled replica of the Chinese Tang Dynasty capital Chang'an, the city became the seat of Japan's imperial court since 794 until Meiji Restoration of 1868, when the capital was moved to Tokyo (City of Kyoto and Kyoto Tourism Council 2010). With roughly 2,000 temples and shrines, including 20% of Japan's National Treasures and 14% of Important Cultural Properties, Kyoto receives over 30 million tourists annually (Kyoto City Local Government 2010). During its time at the center of Japanese power, cultural, and religion, Kyoto accumulated a large collection of palaces, temples, and shrines and was luckily escaped from the bombings of WWII. In modern times, the city is undergoing modernization with some of the older buildings replaced by modern architectures, such as the notorious Kyoto Station complex. The first time visitor to Kyoto would be surprised by the ultramodern glass and steel station and the urban environment all around. Tourism composed a large sector of Kyoto's economy, being constantly visited by school groups from across Japan and many foreign tourists around the world. In a regional brand survey, Kyoto is chosen as the second most attractive city in Japan.

Nara was the capital of Japan from 710 to 784. As formerly discussed, this period of time is

when Japanese national government first being consolidated and Buddhism reached a great prosperity. Nara is left with abundance of Buddhist temples, Shinto shrines, and the excavated remains of the great Imperial Palace, all of which serve as vivid examples of a broad picture of the profound political and social change in eighth-century Japan.

Both Kyoto and Nara are facing the problem of urbanization as a threat of preserving authentic ancient appearance of the cities. With UNESCO world heritage monuments isolated in ultra-modern urban environment, the harmony and integrity of sites of Nara are in threat.

Historic Villages of Shirakawa-go and Gokayama

The historic villages are located in a mountainous region that was cut off from the rest of the Japan mainland for a long time and developed their own housing construction technique. The architectural style unique in the villages is called gassho-zukuri, also known as prayer-hands construction. The thatched and steeply slanting roof resembling hands joined in prayer are exceptionally strong that can withstand the region's heavy snowfalls in the winter. The reason for inscription is attributed to the simple life spirit deeply embedded in the traditional village. The lose touch with nature together with traditional cultivation and silkworms rearing economic system manifests the ideal picture of arcadia.

The designated group of historic buildings is composed of 117 houses and seven other structures. In those buildings and structures, no one actually live there. However, tourists can find a family-operated inns within or nearby these villages to spend a night or two in traditional gassho frame house to experience the life of locals. It is worth to think about the meaning of emptied homes without any residents in these traditional villages. Without the ongoing repairing of homeowners, it is likely that the architecture structure will accelerate their degradation. More importantly, the memories associated with the domestic living and unique social relationships in these traditional villages will be lost.

Itsukushima Shinto Shrine

Itsukushima Shinto Shrine is located on an island in Seto Inland Sea. It has been regarded as a holy place since the sixth century. It was meant to protect people from sea disaster and wars. Painted in red, the shrine contrasts the surrounding mountains and sea environments and illustrates the Japanese concept of scenic beauty, which is a harmonious combination of the power of nature and human.

The most distinguished architecture structure of this shrine is the Torii and Shaden, the symbolizing gate to the shrine and shrine pavilion, both of which are located in the sea. When the seawater is at low tide, it is possible to walk out to the gate.

Like other most visited World Heritage Sites in Japan, the Shinto Shrine is extremely crowded in its peak season, which greatly disturbed the tranquility of its sacredness. How to keep a balance between high visitor density and the serenity of the site and its surrounding environment is a central management issue in Itsukushima Shinto Shrine.

Iwami Ginzan Silver Mine and Its Cultural Landscape

The site is a cluster of silver-bearing mine in the southwest of Honshu Island. The mine reached its peak production in the early seventeenth century of approximately 38 t of silver a year which was then a third of world production. UNESCO considers that the mine contributed to the overall economic development of Japan and Southeast Asia and prompted the mass production of silver and gold in Japan in the sixteenth to twentieth century. The mining area is now heavily wooded, because the silver production from the mine fell in the nineteenth century and eventually closed for low productivity.

The ICOMOS evaluation of the property report (2004) recorded some potential hazards that can have negative impact on the sites. For example, the rural communities are emptied due to low economic vitality. Losing population posed the issue of ongoing conservation of the towns and viability of community. The modern constructions of concrete wharfs and boat rams on the ports changed the authentic appearance of the heritage site.

Sacred Sites and Pilgrimage Routes in the Kii Mountain Range

The site is set in the dense of forests of the Kii Mountains overlooking the Pacific Ocean. The three nominated sacred temple and shrines together with the pilgrimage route linking the sites reflected the fusion of Shito, the ancient local tradition with Buddhism, and the imported religion from China and Korean peninsula. The surrounding environment has a variety of natural beauty, with abundance of streams, rivers, and waterfalls. The site is visited more by domestic tourists, especially the locals, for religious purposes and hiking. The site receives 15 million visitations annually. According to ICOMOS advisory body evaluation (2009), the development surrounding the site is sufficiently controlled by existing law. However, environmental change should be envisaged so that possible damage of typhoons, heavy rains, or landslide can be controlled.

Shrines and Temples of Nikko

Nikko is a small town located in the north of Tokyo and can be easily accessed by trains. A world heritage pass is available for a round-trip to Nikko, including both the transportation pass and the admission to shrines. Therefore, the World Heritage Site in Nikko is an attraction that received high visitation.

The temple at Nikko is famous for its architecture and decorations. Different from other temples and shrines in Japan, it is exceptionally gaudy and decorative, with a strong Chinese decorative style. In 1616, the dying Shogun Tokugawa made his final wish that he would like to be enshrined as a god in Nikko to guard the peace of the land forever.

As shrines and temples, the site received a large number of visitations for the purpose of religion. There is no information about if there is any collision between mass tourism and religious pilgrims. It could be an interesting nice site to investigate the issue.

Heritage Law and Regulations in Japan

Japan has a comprehensive network of legislation for protecting, preserving, and classifying its cultural patrimony. The Law for the Protection of Cultural Properties (1950) is the main legal framework. It protects all the building structures and the area around them. Any alteration to, or activities with adverse effects on the existing condition of, cultural properties designated under the Law for the Protection of Cultural Properties is only permitted with prior permission from the Commissioner of the Agency for Cultural Affairs. When the site is closed surrounded by natural settings, such as the case in Sacred Sites and Pilgrimage Routes in the Kii Mountain Range and Shrines and Temples of Nikko, the Law on Forests, the Law on Rivers, the Law on Sand Control, and the Law on Natural Parks apply. In addition to the national laws, each municipal has its directives in purpose of protecting the assigned areas. The law system is considered by ICOMOS as comprehensive protective measures, serving a carefully developed management plan.

The key cultural sites in Japan are designated as National Treasures or important cultural properties. The National Treasure system is designated by the Agency for Cultural Affairs (a subsidiary of the Ministry of Education, Culture, Sports, Science, and Technology). The national treasure can be buildings and structures or fine arts and crafts, showing outstanding workmanship, a high value for world cultural history, or exceptional value for scholarship. Approximately 20% of the National Treasures are structures such as castles, Buddhist temples, Shinto shrines, or residences). The Agency for Cultural Affairs provides advice on restoration, administration, and public display of the properties.

Discussion

Heritage produces national identity when it receives recognition from official practices. “The moment a place receives official recognition as a heritage site, its relationship with the landscape in which it exists and with the people who use it immediately changes – a place/object/practice ‘outside’ the everyday” (Harrison 2010: 11). When designated as a World Heritage Site, a place became an essential element of national representation, creating symbolic foundations upon which a sense of belonging is based. Therefore, visiting World Heritage Site by domestic tourists is a symbolic mechanism through which

national belonging can be constructed and communicated.

In the case of Gusuku sites and related properties of the Kingdom of Ryukyu, the inscription of this particular site located on the land that received intense territory dispute can be seen as an official declaration that Ryukyu tangible assets in the forms of ruins and monuments, together with the symbolic meanings and spiritual embodiment, are a part of Japanese history and culture. By de-emphasizing the turbulent history of Ryukyu Kingdom as an independent country, or a tributary state of imperial China or a military base for US military, Japan is declaring its control over the land in the past and in the future.

We have taken for granted that each country embodies its own distinctive culture and society so that the terms society and culture are routinely simply appended to the names of nation-states (Gupta and Ferguson 1997). However, national boundaries do not emerge by themselves, but are invented and imposed on a place. Domestic tourism visiting Gusuku sites, a World Heritage Site of Japan, would naturally get the impression that Ryukyu is always a part of Japanese and Ryukyu culture embedded in the site belongs to Japan cultural system. Cabeza (2006) pointed out that heritage is supposed to express the diversity of land and its people not just the heritage linked to the power groups. It is the responsibility of Japanese government to present a full picture of the history and cultural diversity in Gusuku.

Nuryanti (1996) stated that heritage is the carrier of historical values from the past, while tourism is a modern consciousness. The interaction between the two brought the results in a reinterpretation of heritage. In postmodern societies, tourism is conceptualized a series of production-related activities. The central challenge in linking heritage and tourism lies in reconstructing the past in the present through interpretation. Ename charter addressed the need to define the basic principles of interpretation and presentation as essential components of heritage conservation (Silberman 2009). It at the first time addressed the social, economic, and educational dimensions of heritage interpretation. It also defines the interpretation as a complex public exercise of historical reflection among many stakeholders. As such, it attempts to overt the largely one-way mode of communication from experts or professionals to the public at large, but promotes ongoing interpretive process that could and should be carried out by visitors, locals, associated community groups, as well as other stakeholders. In contested sites, as the Hiroshima Peace Memorial (Genbaku Dome), it is particularly important to integrate different interpretations and allows an ongoing discussion of history and future. Projecting Japan as a victim and avoiding the fact that it is also an invader is not only inappropriate but can create dangerous results in the future.

Japanese Archaeological Museums

Kiyohide Saito
Archaeological Institute of Kashihara, Nara Prefecture, Kashihara, Japan

Introduction and Definition

The definition of a museum by ICOM is "a non-profit, permanent institution in the service of society and its development, open to the public, which acquires, conserves, researches, communicates and exhibits the tangible and intangible heritage of humanity and its environment for the purposes of education, study and enjoyment" (ICOM 2012).

In Japan there are 5,775 museums covering such diverse fields as science and technology, art, general exhibitions, as well as zoos, aquariums, and botanical gardens. As of 2011, there are 3,327 historical museums in Japan. With only 1,746 municipalities, every city in Japan averages almost two historical museums within their borders (Ogata 2012a). These numbers show the Japanese people's enjoyment of historical exhibitions which provide an emotional connection to the past and to the land on which people lived.

Japanese historical museums display archaeological artifacts as part of their collections. Since 1970, many historical museums, including archaeological and site museums, have been constructed in line with the increase of archaeological excavations as a result of infrastructural development (Table 1). The current economic crisis has caused difficulties for the management and administration of many museums, including archaeological site museums in Japan.

This entry reviews the present situation of Japanese archaeological museums and their history and discusses the leading principal institutions of Japanese archaeological museums, distinctive archaeological site museums, and city museums with significant archaeological collections.

Historical Background

Before the adoption of the European and American concept of museums during the Meiji Restoration, the Imperial Court, shrines, and temples played a pivotal role in the preservation and administration of precious and religious items. However, these items were not open to the public, only being casually maintained for society.

Japanese Archaeological Museums, Table 1 Number of excavations and museums with years

Number/year	1970	1987	2005	2011
Number of excavations (year)	1,726 (1976)	7,007	8,741	7,934 (2010)
Number of historical museums	473	1,324	3,200	3,327

During the Edo period, members of societies such as Sekitei Kinouchi and Kenkado Kimura displayed collections of rocks of unusual shapes or colors including artificial ancient stone instruments, stone accessories, and archaeological remains (Okada 2012b).

In the last days of the Late Edo period, the Tokugawa shogunate and the Satsuma han (clan) sent delegations to the Paris and London International Expositions. They visited the British Museum and other important museums in Europe during the 1860s. The concept of "museums" returned to Japan with these delegations. However, instead of establishing permanent museums, the Meiji government opted for expositions for industrial development.

In 1870 the Meiji government established the "Department of Products" to oversee the exhibition of industrial products in Tokyo. The government, which was concerned about the preservation of cultural heritage, enacted *the Preservation of Antiquities Act* in 1871. In accordance with this law, many cultural properties, including archaeological remains, were brought into the custody of the department. Later, these archaeological remains were utilized as propaganda to promote the history of the Imperial family.

In 1871 the Department of Museums for the Vienna International Exposition was established. The government expected that the objects collected from around Japan for the Vienna International Exposition would become a useful founding collection for a future museum in Japan. Before being sent to Vienna, the articles were exhibited to the Japanese public at Yushima in 1872. The exhibition was an immense success. At that time the idea of founding a museum was part of a political strategy for the promotion of industry in order to catch up with the West. Thus, the first Japanese museum, based upon the principles of the British Museum in Japan, came about.

In 1875 the Department of Museums was divided between the Ministry of Home Affairs, responsible for promoting industrial development, and the Ministry of Education, Science and Culture, which oversaw school education. When the Ministry of Agriculture and Commerce was established in 1881, the jurisdiction changed once again, and the Department of Museums was transferred to the new ministry. In 1882 a museum simply called "the Museum" was opened in Ueno, which would eventually evolve into the Tokyo National Museum of today. In 1885, the Department of Museums was transferred to the jurisdiction of the Ministry of the Imperial Household to strengthen the protection of cultural properties and art, including archaeological remains, in order to support propaganda promoting the glorious history of Imperial family. The Museum was renamed the Imperial Museum in 1889. At same time, the Imperial Kyoto Museum and the Imperial Nara Museum were founded for same purpose as the Imperial Museum in Tokyo (Seki 2005).

In 1887 the Ministry of Education, Science and Culture also founded a museum in Ueno as the Educational Museum which is now the National Science Museum.

The enthronement of Emperor Showa in 1928 and the anniversary of the 2600th year of the accession of Emperor Jimmu accelerated the construction of museums throughout Japan, both public and private, such as the Museum of Kokugakuin University and the Yamato Japanese Historical Museum (the Museum, Archaeological Institute of Kashihara, Nara Prefecture later).

In 1951, after the World War II, the laws on museums were reformed and the Japanese Association of Museums joined ICOM in 1952. The construction of museums became popular to showcase economic growth (Okada 2012b).

With economic boom following the 1970s, many archaeological museums including site museums were constructed to house and display new discoveries found in large-scale excavations brought about by the nationwide development of infrastructure for transportation. The trend continued until the 1990s.

This boom in museum construction was also stimulated by the announcement by the Agency for Cultural Affairs of the "Project of Fudoki-no-Oka (historical park)" which designated vast areas for archaeological and historical monuments in 1966. Sixteen areas, such as Sakitama, Shimotsuke, Omi, Chikatsu Asuka, Kii, Usa, and Saitobaru, were incorporated as historical parks with archaeological museums. The Agency for

Cultural Affairs encouraged prefectures and municipalities to establish centers for archaeological excavation (Maizo-Bunkazai Center) to protect areas from the rapid increase in the number of excavations caused by development and infrastructure construction in the 1970s and 1980s. There are now more than 60 Maizo-Bunkazai Centers. Although they are not museums, most have exhibition rooms and showcase what archaeology is and how excavation is carried out.

Key Issues

Principal Institutions of Japanese Archaeological Museums

Museums are regulated by the Museum Law of 1951. Museums designated by that museum are facilities for social education. Archaeological museums are also regulated by the 1951 law. There are three types of museum: (1) registered museums, (2) facilities which comply with the appropriate standards, and (3) facilities which resemble these. Registered museums under the jurisdiction of the boards of education of local governments must have a curator and be open more than 150 days a year. Facilities compliant with the standards must be certified by the prefecture, have an associate curator, and be open more than 100 days a year. Facilities modeled on these are not regulated by the law.

The national museum system consists of four museums, the Tokyo, Kyoto, Nara, and Kyushu museums which possess massive archaeological collections. They are not subject to the Museum Law, as they are ranked as facilities for the conservation of cultural properties and so regulated by the Agency for Cultural Affairs (Hamada 2012).

The number of the registered museum is small, with other classes of museum making up the majority. Museums related to archaeological sites are classified as facilities of the third type. These are not regulated by the law. The construction of archaeological site museums is, in most cases, triggered by a new discovery of importance or by the development or the improvement of significant archaeological sites in historic parks. Since the aim of these projects is the development of tourism rather than education, the expense of construction relies on subsidies from the Ministry of Land, Infrastructure, Transport and Tourism together with the Ministry of Education, Culture, Sports, Science and Technology.

Archaeological museums, as well as general museums, have faced financial difficulties, because municipalities have largely adopted the Designated Manager System to reduce annual expenditures. This system has forced head curators to make exhibitions, to conform to popular tastes, and to reduce the number of curators.

With the inclusion of museology in university curricula, many universities have established museums or integrated museums to enable hands-on education in museology and management of museums. Kokugakuin University, Meiji University, Kyoto University, and Kansai University are well-known for their archaeological museums.

Distinctive Archaeological Museums

Museums Put the Word "Archaeology"

Few archaeological museums put the word "archaeology" in the museum's title and display only archaeological remains. These strictly archaeological museums include:

- Ichikawa City Archaeological Museum in Chiba
- Yamanashi Prefectural Museum of Archaeology in Yamanashi
- Hokuto City Archaeological Museum in Yamanashi
- Matsumoto City Archaeological Museum in Nagano
- Kyoto City Archaeological Museum in Kyoto
- Hyogo Prefectural Archaeological Museum in Hyogo
- Tatsuuma Archaeological Museum (private) in Hyogo
- The Museum, Archaeological Institute of Kashihara, Nara Prefecture
- Kurashiki Archaeological Museum (private) in Okayama
- Shimonoseki City Archaeological Museum in Yamaguchi

- The Archaeological Museum Matsuyama in Ehime
- Tokushima Archaeological Museum
- Saitobaru Archaeological Museum in Miyazaki
- Ibusuki Archaeological Museum in Kagoshima
- Kagoshima City Museum of Archaeology in Kagoshima

These museums mainly exhibit archaeological remains that show the historical sequence of events in the area in which they are located.

Among these, the Museum, Archaeological Institute of Kashihara, Nara Prefecture (Fig. 1), is the most distinctive, displaying objects from the Paleolithic to the Medieval period in Nara, an area which played a central role in Japanese political development from the Kofun period (third century CE) to the Nara period (eighth CE). This museum shows how Japan developed as a state and its connection to East Asian countries with archaeological remains excavated over all of Nara prefecture since 1938. This museum was established in 1939 and is the oldest archaeological museum in Japan. Impressive pieces in the collection include:

- Jomon Dogu (earthen figures), the important cultural property, from the Kashihara site (Late Jomon). "Jomon" needs an accent which I haven't got on my computer.
- The drawing on the pottery from the Shimizu Kaze site (Middle Yayoi).
- Prestige objects and gigantic cylinder "haniwa," an important cultural property, from the Mesuriyama mound tomb (Kofun).
- Gorgeous grave goods, a national treasure, including a set of harness, a crown, shoes, and swords from the Fujinoki tomb mound.
- Narrow strips of wood on which messages were written from the Asuka Palace site.
- A bronze epitaph of Ono Yasumaro who edited "Kojiki (Records of Ancient Matters)," an important cultural property.

Yamanashi Prefectural Museum of Archaeology is located in the Kai Fudoki-no-Oka historical park where the Kai-Choshizuka tomb mound and Maruyama tomb mound were constructed late in the fourth century with other small tomb mounds. This museum displays the history of Yamanashi prefecture from the Paleolithic to the Edo period, displaying the remains of the Ichinosawa site, an important cultural property, from the Middle Jomon period and the remains from the Kai-Choshizuka tomb mound and the Maruyama tomb mounds.

Hyogo Prefectural Archaeological Museum is located beside the Onaka site, Yayoi period. This museum also displays the history of Hyogo

Japanese Archaeological Museums, Fig. 1 The Museum, Archaeological Institute of Kashihara, Nara Prefecture

J

prefecture from the Paleolithic to the Edo period. The integration of exhibits for children plays an important role at this museum.

Saitobaru Archaeological Museum in Miyazaki prefecture is located at Saitobaru Fudoki-no-Oka historical park, where more than 311 tomb mounds exist. This is an archaeological site museum featuring a cluster of Saitobaru mounds designated as a national special historical park and exhibits archaeological remains to introduce the history of Miyazaki prefecture from the Paleolithic to the Edo period. The main focus of this museum is to display archaeological remains related to trade between Miyazaki and East Asia.

Ibusuki Archaeological Museum in Kagoshima prefecture is a municipal museum which displays the history of the southern Kyushu "Hayato" area with archaeological remains and emphasizes the Hashimurekawa site which was buried as a consequence of volcanic eruptions of Mt. Kaimon in the Jomon period and the Yayoi period.

Tatsuuma Archaeological Museum is a private museum which was established by the Hakutaka sake brewer. The collection of *Dotaku*, a bell-shaped bronze vessel of the Yayoi period, is its centerpiece.

Museums for Specific Periods

There are large-scale archaeological museums which exhibit archaeological remains of specific periods, such as the Museum of Yayoi Culture in Osaka, the Osaka Prefecture Chikatsu Asuka Museum, and Kumamoto Prefectural Ancient Burial Mound Museum.

The Museum of Yayoi Culture in Osaka is the largest museum of its subject period in Japan showing the evolution of the Yayoi clan that constructed large tomb mounds in the transition to the Kofun period.

The Osaka Prefecture Chikatsu Asuka Museum (Fig. 2) in the Chikatsu Asuka Fudoki-no-Oka historical park centers on the Kofun period, displaying a diorama of how the largest tomb mound called Daisen tomb mound (or Nintokuryo-Kofun) was constructed.

Kumamoto Prefectural Ancient Burial Mound Museum concentrates on tomb mounds with decorative murals, drawn on the walls of their stone chambers around sixth century CE. This kind of

Japanese Archaeological Museums, Fig. 2 The Osaka Prefecture Chikatsu Asuka Museum

tomb was commonly constructed in northern Kyushu and provides visitors with a special impression of the tomb mounds.

Other Museums

As of 2011, there were 5,775 museums in Japan, of which 3,327 are historical in scope, and most of these display archaeological artifacts. While belonging to the third category and not regulated by the Museum Law, they are nonetheless important for the preservation of Japanese culture in the face of the modern construction which endangers the remains of our past.

There are 1,746 municipalities in all, with about 3,000 historical museums in Japan today. Among the many museums, mainly the displaying distinctive archaeological remains of their locality are the Hokkaido Museum of Northern Peoples, the Tohoku History Museum, the Osaka Museum of History, the Hiroshima Prefectural Museum of History, the Shimane Museum of Ancient Izumo, Kyushu Historical Museum, and the Okinawa Prefectural Museum. Every prefecture has founded museums to preserve their history and to display archaeological remains from all periods up to the Edo period to inform their visitors of the historical past.

The Hokkaido Museum of Northern Peoples is located in Abashiri, in northern Hokkaido, and preserves the Okhotsk culture which flourished around the seventh and eighth century. Discoveries from Moroyo shell midden are impressive and show the cultural exchange between this area and northern East Asia.

The Tohoku History Museum in Miyagi is located in a suburb of Sendai and displays archaeological remains from the ancient culture in the Tohoku region. This museum focuses on the system of ancient administration during the Nara period around the eighth century.

The Hiroshima Prefectural Museum of History focuses on the life of the people of the Setouchi area, with the archaeological remains of "Kusado Sengen," a medieval port town covered by a river. A life-size reconstruction of street life in "Kusado Sengen" recreates a summer evening during the Muromachi period and is popular with visitors.

Archaeological Site Museums

There are many archaeological museums which were constructed as guidance facilities to archaeological sites which are preserved in archaeological parks. Most site museums are constructed as atonement for destruction of the sites by development. Distinctive archaeological site museums include:

- Tokoro Iseki no Yakata (Tokoro Site Museum) in Hokkaido
- Sannai Maruyama site (Sannai Maruyama Exhibition Hall) in Aomori
- Goshono site in Iwate
- Tomizawa site (Chitei no Mori Museum) and the Historical Museum of Jomon Village Okumatsushima (Satohama shell midden) in Miyagi
- Iwajuku site in Gunma
- Shibayama tomb mound (Shibayama Kofun Haniwa Museum) in Chiba
- Otsuka-Saikachido site (Yokohama History Museum) in Kanagawa
- Shakado site (Shakado Museum of Jomon Culture) in Yamanashi
- Togariishi site and Hiraide site (Togariishi Museum of Jomon Archaeology) in Nagano
- Toro site (Shizuoka City Toro Museum) in Shizuoka
- Nishitani tomb site (Izumo Yayoinomori Museum) in Shimane
- Mawaki site in Ishikawa
- Saiku site (Saiku Historical Museum) in Mie
- Karako-Kagi Archaeological Museum and Heijo Palace site in Nara
- Myokenyama tomb mound (Onishi Fujiyama History Museum) in Ehime
- Hirabaru site and Mikumo sites (Itokoku History Museum) in Fukuoka
- Haranotsuji (Iki City Ikikoku Museum) in Nagasaki
- Oji site in Kagoshima

The Tokoro Iseki no Yakata no Mori Park (Tokoro Site Museum) is located in Kitami City in northern Hokkaido. At the Tokoro site, there are more than 10,000 archaeological features consisting of 2,500 pit houses, which date from

Japanese Archaeological Museums, Fig. 3 Shakado Museum of Jomon Culture

2,000 BCE to 1,000 CE. This is one of the largest pit house sites within a single autonomous area in the world. The park is divided into four parts: a site, a municipal museum which displays remains from all over this city area, a municipal research center with a repository open to the public, and the Tokyo University Tokoro Site Museum displaying remains from excavations conducted since 1957.

The Sannai Maruyama site was designated as a special national historical site in 2000 and is one of the largest archaeological parks in Japan. Excavations carried out since 1992 have brought uncovered dwellings, pillar-supported structures, graves, storage pits, clay mining pits, and road refuse disposal pits with large numbers of artifacts. There is an exhibition hall called "Jomon Jiyuukan," and numerous Jomon houses, storage pits, and six-pillared buildings are reconstructed in the park.

The Tomizawa (Chitei no Mori Museum) site is located in Sendai, Miyagi. This museum allows visitors directly to see excavated lithics and traces of bonfires in woodland from the Paleolithic period and feel the atmosphere of the forest of 20,000 years ago.

The Shakado Museum of Jomon Culture (Fig. 3) in the Shakado site is located in Fuefuki City, Yamanashi Prefecture. Most of the site was destroyed with construction of the Chuo Expressway, but the Shakado Museum of Jomon Culture was constructed to show the greatness of the site which flourished, about 5,000 years ago, in the Middle Jomon period. As this museum is located beside the Shakado service area, visitors can get to the museum with only a 3-min walk. The museum exhibits magnificent Jomon clay figures with over 1,116 pieces on display and beautiful Jomon pottery designated as important cultural property. The museum also has a wonderful view of the Southern Alps.

The Togariishi Museum of Jomon Archaeology is located beside the Togariishi site from the Middle Jomon period (3,000 BCE). The museum exhibits over 200 splendid archaeological artifacts. There are two outstanding clay figures, "the Jomon Venus," a national treasure, and "the Venus of Mask," an important cultural property,

Japanese Archaeological Museums, Fig. 4 Shizuoka City Toro Museum and the reproduction of the rice cultivation in the Yayoi rice paddy fields

exhibited as special-featured items. Outside the museum there are six pit dwellings excavated at the Yosukeone site and reconstructed to show the Jomon village landscape.

The Shizuoka City Toro Museum (Fig. 4) at the Toro site designated as a special national historical site is located in the center of Shizuoka City. The site and the museum are surrounded by modern houses due to urbanization. The Toro site was discovered in 1943 and was largely excavated from 1947 to 1950 and from 1999 to 2004. Through the excavations, a Yayoi-era village consisting of pit dwellings, elevated rice storehouses, and about 8 ha of rice fields with various water facilities was unearthed. Many pottery and wooden vessels, utensils, and farm implements were also discovered. The museum in Toro not only displays archaeological artifacts from the site but also features activities allowing visitors to get a real feel of what life at the site must have been like. Staff of the museum provide activities for visitors, such as cultivating rice fields, making a fire, weaving cloth, and making a pottery.

The Mawaki Jomon Museum (Fig. 5) is located in Noto Town in Ishikawa and introduces the Mawaki site. This site was a village from the Early to the Latest Jomon period (6,000–2,200 years ago). Remains including pottery, wooden objects such as oars, pillars as a totem pole and vessels, plant knitting and ropes, and animal bones from dolphins, fish, deer, and wild boars were found. Beside the settlement area, there was a wooden circle which consisted of huge pillars and graves. The museum in the Mawaki site displays artifacts to indicate a rich Jomon life. A wooden circle has been set up as a symbol to express a ceremonial connection to the Jomon people in the Mawaki site.

The Heijo Palace site designated as a special national historical site in Nara was the capital of Japan 1,300 years ago, from 710 to 784. In the early eighth century, Japan established very powerful centralized bureaucratic government by adapting the highly developed Chinese constitution. The ancient Heijo Palace was located in the northern center of the capital. It was surrounded by earthen walls. In the palace, there were an Imperial residence and the government administrative buildings. The Heijo capital was modeled after Chang'an, the capital city of the Chinese Tang dynasty. There are two museums at the palace site. One is an open air museum showing the royal buildings after the excavation. The other one shows the life of the palace. The remains of the palace and the surrounding area were designated as a UNESCO World Heritage Site in 1998.

The Myokenyama tomb mound, located on the top of a hill in Imabari City, Ehime Prefecture, was constructed in the late fourth century, when the Yamato clan was spreading their power over Japan. Its mound is a keyhole-shaped tomb mound covering two stone burial chambers with vertical access as the place for interments. A Chinese bronze mirror accompanied the dead.

Japanese Archaeological Museums, Fig. 5 Mawaki Jomon Museum

The Onishi Fujiyama History Museum was founded at the Myokenyama tomb mound and only displays remains from that tomb. Visitors can easily understand how the dead were disposed and view the burial chambers through glass windows on the top of the tomb mound.

City, University, and Other Museums with Significant Archaeological Collections

City Museums

City museums are noted for their large-scale exhibitions designed to attract the public. These museums have been able, with their substantial budgets, to collect important archaeological material. City museums with important archaeological collections include:

- Tokyo National Museum
- National Museum of Japanese History in Chiba
- Osaka Museum of History in Osaka
- Kobe City Museum in Hyogo
- Fukuoka City Museum in Fukuoka
- Kyushu National Museum in Fukuoka

The Tokyo National Museum (Fig. 6), as Japan's oldest museum, has an extensive and excellent collection built largely before the national expansion of museums from the 1960s. There are many designated "national treasures" and "important cultural properties" on display.

Jomon clay figures called "Dogu" of various types and periods show beautiful postures such as the Dogu from the Shimpukuji shell midden in Saitama and the Kamegaoka site in Aomori. Many bell-shaped bronze vessels of the Yayoi period called Dotaku are shown including a Dotaku with decorative animal and human motifs from Kagawa; these objects are famous for understanding agricultural ceremonies in the Yayoi period. A collection of bronze mirrors from the Kofun period aids people in understanding the formation of ancient Japanese political systems. Objects from Eta Funayama tomb mound such as a sword with a silver inlaid inscription are indispensable archaeological evidence for understanding East Asian history. From the Asuka period around the sixth century, ritual objects used in the consecration of the building site of a five-storied pagoda at Horyu-ji temple are important not only for religious studies but also as evidence of the technical art of the time. The Kobe City Museum in Hyogo possesses bronze objects from the Sakuragaoka site in Kobe. These bronze objects consist of 14 Dotaku with crossed-band and running water designs and seven bronze halberds. This collection is essential for study of the Yayoi society.

Japanese Archaeological Museums, Fig. 6 Tokyo National Museum

University Museums

University museums have a different role from the city museums but also preserve large and significant archaeological collections. The Hokkaido University Museum, the University of Tokyo Museum, Kyoto University Museum, the Meiji University Museum in Tokyo, the Kokugakuin University Museum in Tokyo, the Kansai University Museum in Osaka, and the Tenri University Sankokan Museum in Nara possess large collections for research and education.

The Hokkaido University Museum possesses archaeological objects from all over Hokkaido before the arrival of the Ainu and material of the Okhotsk culture.

The Tokyo University Museum possesses a fine collection of archaeological objects from all over the world, especially East Asia, West Asia, and South America where the university has sent research expeditions. This university's collections from the Jomon and Yayoi period are outstanding and demonstrate how archaeology developed as an academic field in Japan.

Kyoto University Museum (Fig. 7), the first university where archaeology was accredited as a subject in Japan, has a great collection of archaeological remains collected through many excellent excavations in West Japan, such as the Karako site in Nara; the Ikisan-Choshizuka tomb mound in Fukuoka; the Tsubai-Otsukayama tomb mound in Kyoto; the Shikinzaka tomb mound, the Kyozuka tomb mound, and the Minami-Tenpyozuka tomb mound in Osaka; and the Ishiyama tomb mound in Mie.

The Kansai University Museum possesses the collection of Mr. Hikoichi Motoyama, former president of the Mainichi Newspaper Company, from among others, the Koho site in Osaka, Jomon pottery from the Korekawa in Aomori, and a stone pillow for the dead, Early Kofun period, from the tomb attributed to Andonyama (Sujin Emperor) tomb mound.

The Tenri University Sankokan Museum in Nara possesses a large number of archaeological objects from Japan, China, Korea, West Asia, and South America. The most varied collection among them are the archaeological remains from the Furu site, which were connected to the ancient powerful clan "Mononobe" and are important in understanding ancient power structures.

Other Museums

There are many more museums affiliated with shrines and temples possessing archaeological remains as religious treasures. One of the most important archaeological collections is in the Munakata Taisha Shinpokan (Munakata Shinto Shrine) in Fukuoka. There are relics from the Okitsumiya shrine in Okinoshima Island on the Genkainada of the Japan Sea. The Okitsumiya

Japanese Archaeological Museums, Fig. 7 The Kyoto University Museum

shrine belongs to Munakata Taisha and was excavated in the 1960s.

Future Directions

Since the establishment of the Tokyo National Museum in 1882, many Japanese archaeological museums have been founded and have grown as historical museums. Land development and transportation infrastructure construction increased the number of excavations nationwide as new and magnificent archaeological artifacts were discovered. Many archaeological site museums have been constructed with tourism in mind. However, the economic crisis has placed museum managers and museums generally under stress. Museums have to think about how to survive this new economic climate while still serving their communities and missions.

Java Man

Russell L. Ciochon[1] and O. Frank Huffman[2]
[1]Department of Anthropology, University of Iowa, Iowa City, IA, USA
[2]Department of Anthropology, University of Texas at Austin, Austin, TX, USA

Introduction

"Java Man" is the informal name given to Pleistocene *Homo erectus* inhabitants of Java. The

Java Man, Fig. 1 The Java Man (*Homo erectus*) fossil localities described in the text: Ngandong (Ng), Mojokerto (Mo), Sangiran Dome (Sg), and Trinil (Tr); Song Terus cave (St) has Paleolithic artifacts but no *Homo erectus* fossils. (After Huffman et al. 2012. © Frank Huffman, Univ. of Texas)

fossil discoveries on the island include the first for this extinct species, which is now known to have been widely distributed across the temperate and tropical zones of the Old World (see ▶ "*Homo erectus*"). Today, more than 100 skeletal specimens have been attributed to this species from localities in Central and East Java (Fig. 1; Indriati 2004). No other confirmed specimen of *Homo erectus* is known from elsewhere in Southeast Asia; however stone tools indicate the presence of early hominins on other islands in Southeast Asia suggesting a wider distribution of *Homo erectus* (see ▶ "Insular Southeast Asia in the Lower Paleolithic").

It is unclear how *Homo erectus* communicated: whether they "spoke" in any manner or used gestural communication. Nor do we know how meaningful a twenty-first-century person would find the facial expressions of Java Man. We also have not resolved how *Homo erectus* social groups were organized, how they divided labor among group individuals, or how exactly they subsisted. On the other hand, the physical attributes of Java Man are reasonably well established. The average *Homo erectus* stood about 1.7 m (5 feet, 6 inches) tall and had a lanky torso with long, well-muscled limbs and nimble hands. Java Man's brain was about three-quarters of the size of a modern human's brain (1000 cm^3 versus 1350 cm^3, respectively). *Homo erectus* individuals had flattened foreheads with prominent brow ridges (Fig. 2). The rear part of the skull (occipital bone) was curved sharply inward toward its base and had a massive ridge (transverse torus) where strong neck muscles attached. The lower jaw was nearly chinless. The face was massive, giving the head more of a forward projection (prognathism) than *Homo sapiens*. Java Man's teeth, on the whole, were only slightly larger than those of modern humans, and their incisors were "shovel-shaped" on the tongue side. Despite this human-like appearance, Java Man would have stood out in a crowd of our contemporaries.

Definition

"Java Man" refers to representatives of *Homo erectus* that inhabited Java, Indonesia, during the Pleistocene. In the early 1890s, the Trinil site

Java Man, Fig. 2 Sangiran 17, the most complete cranium of Java Man (*Homo erectus*). © Russell L. Ciochon, Univ. of Iowa

produced the holotype fossils of *Homo erectus* (the specimens that constitute the prime reference material used in defining *Homo erectus* taxonomically).

Key Issues/Current Debates/Future Directions/Examples

In the following paragraphs, we describe the best-known Java Man sites of eastern Java (Fig. 1) and use them to highlight the current scientific issues concerning *Homo erectus*.

Trinil

The Trinil discovery was the result of the only deliberate search for a fossil ape-human "missing link" in the nineteenth century. Eugène Dubois, a Dutch doctor who was strongly influenced on the subject of evolution by the German biologist Ernst Haeckel, hypothesized that fossils of the ape-human lineage could be found in Southeast Asia (see ▶ Dubois, Eugène). Dedicated to testing his hypothesis, Dubois joined the Dutch Army as a surgeon stationed in the Dutch East Indies (present-day Indonesia; Shipman 2001). In 1888,

Java Man, Fig. 3 Trinil I, the first cranium (skullcap) of Java Man discovered by Eugene Dubois. © Russell L. Ciochon, Univ. of Iowa

he began scouring limestone caves and outcrops of volcanic-rich sedimentary rocks known to have produced mammalian remains (de Vos 2010). Within 2 years, in October 1891, while digging in vertebrate-fossil-bearing sandstone exposed along the Solo River at Trinil (Tr on Fig. 1), his field crew discovered a large, fully fossilized, ape-like skullcap (Fig. 3). The following year, the field workers unearthed a humanlike adult thighbone (femur) about 12 m away from where the skullcap had been found and in the same meter-thick bonebed. Dubois asserted that the two specimens were from the same individual (although, surprisingly, debate continues on if the femur is the same species as the skullcap, Ruff et al. 2015; see also Joordens et al. 2014). Based on the two fossils, Dubois defined a new species, *Pithecanthropus erectus* (meaning "upright ape-man") – the very kind of creature he went to the East Indies to find. In the 1940s, *Pithecanthropus erectus* was subsumed into the human lineage as *Homo erectus*, after anatomical comparisons with other known hominin fossils made it clear that the Java finds were more human- than ape-like.

Excavation of the Trinil discovery bed (sometimes referred to as the Hauptknochenschicht or Trinil HK) ultimately produced thousands of strongly fossilized bone fragments of animals that had lived alongside *Homo erectus* in the local Pleistocene paleoenvironment. Most of the fossils represent extinct forms of cattle, water buffalo, deer, *Stegodon* (an elephant-like proboscidean), pig, rhinoceros, and tiger (de Vos 2010). Also present were denizens of large

lowland rivers and estuaries, such as crocodiles, turtles, and catfish (Joordens et al. 2009). The Trinil bonebed is often attributed to the late early Pleistocene (circa 900,000 years ago) on the basis of the correlation of its fauna with similar species at the Sangiran Dome (see below). Despite having contained multiple *Homo erectus* fossils and thousands of other large fossils, the Trinil discovery bed produced no stone tools. However, fossil freshwater mussel shells from Trinil show evidence of shellfish consumption, tool use, and even geometric engraving (Joordens et al. 2014). Minerals associated with the shells provided dates of 540,000–430,000 years ago using $^{40}Ar/^{39}Ar$ and luminescence dating methods.

Ngandong

In 1931–1933, the Geological Survey of the Netherlands Indies uncovered 12 cranial and two tibial (shinbone) fossils of *Homo erectus* along with more than 25,000 nonhuman fossils at Ngandong (Ng on Fig. 1). The fossils were unearthed across an excavation of about 4600 m^2 from gravelly sand (Huffman et al. 2010). This discovery bed is about a half-meter thick in a stratum near the base of flat-lying river-terrace deposits having a stratigraphic thickness of about 3 m (Fig. 4; Ciochon et al. 2009). The fossils were predominantly disarticulated and fragmented, with extinct cattle being the most common among 10 other mammals, turtle, and crocodile.

Ngandong is notable among global paleoanthropological sites because not only is it extraordinary to encounter the fossilized remains of so many hominin individuals in a single river-laid bonebed, but *Homo erectus* at this site appears to have been contemporaneous with anatomically more evolved *Homo* species from mainland Eurasia and Africa. Ngandong has been dated using paleontological and geological relationships, as well as radioisotopes. Paleontologically, the Ngandong nonhuman fossil assemblage includes more living taxa than was found at Trinil, indicating that Ngandong is the younger of the two accumulations, but the Ngandong assemblage also has extinct elements that do not occur in the modern fauna of Java or even in the youngest premodern assemblages (de Vos 2010). Geologically, the Ngandong deposit is flat lying, rather than being structurally tilted in the way that other *Homo erectus* formations in eastern Java normally are. On the other hand, the bonebed accumulated along the Solo River streambed before it entrenched to its present-day level, some 20 m below the site. Radioisotopic age estimates vary from 53,000–27,000 years (Swisher et al. 1996) to older than 70,000 years (Yokoyama et al. 2008) and younger than 500,000 years (Indriati et al. 2011). The 1931–1933 *Homo erectus* discovery bed was re-excavated in 2008 and 2010 in an effort to help clarify its age and explain how so many human individuals came to be embedded in the Solo River sands at this one locale (Ciochon et al. 2009). Flaked stone artifacts have been reported recently from a terrace deposit situated at the same elevation above the Solo River, 5 km south of Ngandong, and the artifact bed appears to date from ~102,000 to 130,000 years ago using red TL on the associated fluvial sediments (van den Bergh et al. 2014).

The bones of *Homo erectus* and the other animals were probably deposited during a flood on the Solo River that originated with rains falling on a stratovolcanic mountain >50 km away; the flooding followed a mass death of large mammals that had aggregated along the Solo River (Huffman et al. 2010). The Ngandong event was one episode in an apparently consistent million-year-long paleogeographic pattern: the well-watered river valleys of the stratovolcanoes sustained recurring or continuing habitation of *Homo erectus*, cattle, deer, *Stegodon*, and other large-bodied herbivores, while rapid volcaniclastic deposition, at times following eruption-related death, promoted quick burial and preservation of skeletal remains (Huffman et al. 2012).

Mojokerto

The Mojokerto site was discovered in 1936 approximately 125 km east of Ngandong and Trinil (Mo on Fig. 1). Unlike the previous finds, the Mojokerto site was a small excavation and produced just one, though considerably important, specimen attributable to *Homo erectus*. The

Java Man, Fig. 4 *Homo erectus* bonebed at Ngandong, 1931–1933. (**a**) The bonebed is exposed across an excavation platform with pedestals at its edge awaiting fossil collection. (**b**) A *Homo erectus* skullcap (calotte with basal margins; to the left of the matchbox) before geologist W.F.F. Oppenoorth removed it from the bonebed in March 1932. (After Huffman et al. 2010. © Joke Oppenoorth, The Netherlands)

fossil is the cranium of a juvenile, a rare occurrence in early hominin sites. Also, the Mojokerto child skull was embedded in conglomeratic sandstone deposited by a river flowing through a marine delta, making it the only seacoast geological context known for *Homo erectus* (Huffman et al. 2006). Finally, a probable early Pleistocene age places it among the earliest hominin specimens from Asia. Despite the potential value of establishing an exact absolute date for Mojokerto, radioisotopic and paleomagnetic investigations have so far not achieved this objective.

While the accurate dating of Mojokerto and many other Java *Homo erectus* finds remains a scientific challenge, recent research on the discovery sites improves our understanding of one characteristic of the *Homo erectus* presence in eastern Java. Andesitic sand and gravel largely make up the *Homo erectus* formations and form the matrix around the Ngandong, Mojokerto, and Trinil *Homo erectus* specimens (as it does for many finds from Sangiran Dome, described below). The paleogeographical implications, especially clear in the 125-km-long formational outcrop belt that connects Trinil to Mojokerto, are that the eastern Java sites record hundreds of thousands of years of human existence along large rivers flowing off of stratovolcanic peaks in a paleolandscape that was quite similar to eastern Java today (Huffman et al. 2006, 2010, 2012; the volcanic peaks form highest elevations in the Digital Terrain Model that is used as the base map in Fig. 1). The stratovolcanoes of the *Homo erectus* period, like those in modern Java, often generated perennial river discharge (continuous flow fed by the mountainous concentration of rainfall) as well as periodic eruptions of voluminous volcanic material; the runoff and sediment combined to produce volcanic-derived sedimentary pulses, including slurries and sandy-gravelly floods that ravaged the river valleys for many kilometers downstream (Huffman et al. 2012).

Java Man, Fig. 5 The Bapang maxilla from Sangiran, the earliest firmly dated fossil evidence of Java Man: A, Occlusal view; B, Lateral view (Zaim et al. 2011). © Russell L. Ciochon, Univ. of Iowa

Sangiran Dome

Vertebrate fossils have been collected since the mid-nineteenth century at the Sangiran Dome (Sg, Fig. 1), 65 km west of Trinil, but it was not until 1937 that G.H.R von Koenigswald, a paleontologist with the Geological Survey of the Netherland Indies, made the first of many *Homo erectus* finds there. Today, more than 80 specimens, or over 77% of all Indonesian fossil humans, derive from Sangiran Dome (Larick et al. 2001; Indriati 2004). Among the specimens is the most complete skull of Java Man known (Sangiran 17; Fig. 2). The word "Dome" in the name of the discovery area refers to the ovoid 4 by 8 km geological uplift (a structural dome) that exposes the fossiliferous beds. Many sites and stratigraphic discovery levels occur here, in contrast to the Ngandong, Mojokerto, and Trinil sites, where each discovery came from a single bed extending laterally less than a few hundred meters. Because the finds from Sangiran Dome are so important to the paleoanthropological record of Asia, UNESCO added the "Sangiran Early Man Site (Indonesia)" to the World Heritage List in 1996.

Sangiran Dome continues to yield both new *Homo erectus* finds and scientific insights into the evolutionary history the species. We highlight three examples. First, a 1.5 million-year-old *Homo erectus* upper jawbone (Fig. 5) from Sangiran Dome, when compared to *Homo erectus* material from China, Africa, and Georgia (central Asia), as well as with *Homo habilis* remains from Africa, seems to indicate that *Homo erectus* in East and Southeast Asia came from two separate populations. Evidently there was an early influx that reached Java and a later one that populated China (Zaim et al. 2011). Second, Sangiran Dome has been the site of a series of excavations in the last 40 years, and one of these (Ngebung) revealed several lithic artifacts and cut-marked bones along a Pleistocene ground surface (Semah and Semah 2006). This discovery is the best evidence yet of how Java Man used stone tools (Fig. 6). Equally, the finds serve to underscore how rare lithic artifacts and cut-marked bones are in *Homo erectus* beds of eastern Java, even in the prolific bonebeds excavated at Ngandong and Trinil. Third, because the geology of Sangiran Dome has been studied more intensely than other hominin-producing outcrop areas, it offers unique perspectives on the paleoenvironmental context of Java Man. The nature of the ancient soils and carbon isotope studies indicate that the earliest *Homo erectus* at Sangiran Dome encountered a low-relief lake-margin landscape dominated by moist grasslands with open woodlands in the driest landscape positions, while later in the Pleistocene, the hominin landscape had more riparian forests, local savanna, and open woodland (Bettis et al. 2009; Brasseur et al. 2015).

Several other sites in eastern Java help to show the extent of early hominin occupation in eastern Java. Hominin fossils were found with typical Pleistocene fauna at Patiyam, 90 km north of Sangiran Dome. Paleolithic artifacts (but no hominin fossils)

Java Man, Fig. 6 Stone artifacts from Ngebung, Sangiran: A, retouched flake; B, polyhedron tool. (Courtesy of © by Francois Semah, CNRS, France)

occur near Java's Indian Ocean coast in Song Terus cave, 75 km southeast of Sangiran Dome (St on Fig. 1; Semah and Semah 2006).

Summary

Both the origin and extinction of Java Man are subjects of continuing research. An East Asia source for Java Man was the leading scientific theory until the ascendency of African paleoanthropology during the 1960s. After that, the inferred origins and taxonomy of *Homo erectus* focused on Africa. Java Man represented a distant way point of an African-sourced dispersal. Interest now rests in a balance between African and Eurasian paleoanthropologic evidence. Particularly influential have been the discoveries of *Homo erectus georgicus* at Dmanisi, Republic of Georgia; Homo floresiensis, the "hobbit," of Flores Island, 1000 km east of Java; and the Denisovan populations of Northeast Asia (see *Dmanisi* in ▶ *Homo erectus*). *Homo erectus* or related ancestors inhabited western Asia more than 1.8 million years ago, as indicated by the fossils of this age at Dmanisi. *Homo erectus* likely reached Java by 1.6 million years ago upon evidence from the Sangiran Dome and possibly Mojokerto (Larick et al. 2001; Zaim et al. 2011). Even if Java Man emerged from an eastward-dispersing population of African origin, *Homo erectus* on the whole might have been most numerous in southern Eurasia with Java Man being one component of this widespread population. Whether Java Man was contemporaneous with *Homo sapiens*, as it dispersed out of Africa to Southeast Asia and Australia at around 40–60 thousand years ago, is not resolved. Firm dating of the Ngandong *Homo erectus* offers one opportunity to test this possibility.

Jenne-Jeno, Archaeology of

Roderick J. McIntosh
Department of Anthropology, Yale University, New Haven, CT, USA

Introduction

Jenne-jeno is an ancient city in the Middle Niger floodplain of the Niger River in present-day Mali. It was the first indigenous city recognized in Africa south of the Sahara, contradicting the long-held assumption that African cities were initially colonies of or in some way stimulated by Greco-Roman, Punic, or Egyptian urbanism north of the desert. It is the signature African site in one of many urban landscapes around the world that have pressed in new dimensions the debate about the degree to which centrally organized, hierarchical or horizontally organized, "distributed" cities deal better with resilience, sustainability, and demographic expansion (Anderson and Rathbone 2000; Crumley 1979). Jenne-jeno is one of scores of specialist-occupied settlements, separate but clustered together in an original city plan labeled the Jenne-jeno Urban Cluster. Notable also is the lack of evidence to date for kings, state apparatus, and indeed for a hierarchical power structure. Although other Middle Niger cities are coming to light that apparently predate this site's third-century foundation, Jenne-jeno serves for africanists as the type site for heterarchical (nonhierarchical) authority at an early city.

Definition

Early African city lacking expected evidence of kings and hierarchical power apparatus, all things once thought to be necessary to bind together the inhabitants.

Key Issues/Current Debates

Jenne-jeno rises seven meters high over Mali's Middle Niger floodplain (Fig. 1), a *tell* that would not be out of place in Mesopotamia. Jenne-jeno's descendant town, Jenne, lies three kilometers away; its present-day inhabitants walk about on nine meters of ancient city deposits. Within four kilometers are seventy tells in total, apparently all occupied contemporaneously with Jenne-jeno, and most abandoned at the same time, around AD 1400 (R. McIntosh 1998 & 2005). Many were founded simultaneously with Jenne-jeno in the third century B.C. In fact, in the 55,000 square kilometers of the seasonally inundated Middle Niger floodplain, there are many hundreds of similar mounds. In the roughly 170,000 square kilometers that were flooded yearly within the past four to five millennia (much now in the deepest Sahara), there are hundreds of tells more. Yet, as recently as the mid-1970s this was not recognized as an urban landscape.

During Colonial times, multiple archaeologists walked over the site (Mauny 1961), missing entirely its age and significance, because utterly lacking on the surface were palaces, temples, and other indicators of "civilization." As we shall see, Jenne-jeno is indeed a "city without citadels" – and that is its greatest importance to world prehistory. Later, in the late 1970s, archaeologists came armed with new theory and excavation and survey methodologies that allowed them first to recognize and then to plumb the evolution, not just of city Jenne-jeno, but of what we now call the "Jenne-jeno Urban Complex." As large and as heterogeneous as the principal site was, it was only a part of a 70-site cluster that, together, provided urban services and manufactures to a hinterland of many thousands of square kilometers – and ultimately to the sister-city of Timbuktu over four hundred kilometers downstream at the Saharan fringe.

From its foundation, Jenne-jeno served as the focus of long-distance trade networks that linked gold and forest goods producers far to the south with those who brought the semi-precious stone and salt of the Sahara (and eventually metal goods, beads, and books from North Africa). The growth of the town is a story of ever growing numbers of craftspersons adding value to the raw materials brought by traders and building a vast exchange covering large parts of the Middle Niger

Jenne-Jeno, Archaeology of, Fig. 1 Location of Jenne-jeno and of the Jenne-jeno Urban Cluster in the Middle Niger of Mali, West Africa. Numbers associated with sites of the Clusters denote numbers of units excavated (e.g., 22 = Jenne-jeno)

and western Sahel. The relative homogeneity of the ceramic assemblages over this vast area attest to the commercial strength of the town (S. McIntosh 1995), a dominance that appears not to have been matched by any political hegemony.

Archaeologists once denoted a city by its citadel and palace, the associated residences of the elites, and the splendid temples in which kingship and its relation to the gods was celebrated (Yoffee 2005). Curiously, at Jenne-jeno no elite residences, no public architecture nor monuments, much less a king's palace have been located despite extensive excavation. What the site does provide in ample volume is evidence of multiple occupations, multiple manufacturing areas and multiple "identity groups" as indicated by a great diversity of contemporaneous burial practices. After some 35 years of controlled stratigraphic excavations at some 22 units spread over the 33 hectare area of the site, we have a plot of how that occupational and identity diversity burgeoned from the relatively simple (yet quite large at 20 hectare) community at its founding in the third century B.C. Note that sinking so many excavation units, some as large as 10 meters by 6 meters, into the 7 meter (and more) deep deposits is absolutely necessary when one is investigating the emergence and evolution of complex society, that is, complex mix and dynamics of interactions of multiple corporate groups (defined as self-identified groups that hold real or symbolic property in common).

Sinopoli et al. (2015) discuss the concept of the "distributed" cities, those in which power and authority appear to be arrayed quite differently that in the "classic" Mesopotamian urban seats of kings, militarized control agencies, and

hierarchical bureaucracies. The more horizontal distribution of decision making, however, raises its own set of questions about how these populations respond to crises (when a lag in response may have dire consequences), if there are "natural limits" to absolute population size or to the numbers of autonomous ethnic or corporate groups that can be integrated and, ultimately, can distributed power endure?

A complication to the archaeologist's tasks is the tight clustering of nearby settlements in a density that roughly decreases with distance from the principal site. What does clustering mean? One way to answer that question is to surface collect artifacts and surface features (burials, house foundations, etc.) from all the sites in order to ask the question: are there anomalous concentrations of certain artifacts or features, compared to the range and relative proportions at Jenne-jeno that reveal special activities concentrated at different locales? Take the case of iron smelting. This is a dirty, hot, and noisy activity, one that is today locally associated with the production of highly dangerous occult power. Not something one wants next door. Through the Jenne-jeno sequence, we see the migration of smelting from the focus site to multiple satellites. Adding to the tasks of sampling the activities at the main site, the urban archaeologist also must study the activities in each of the satellite sites. Already in the first season of surface collection in the Jenne-jeno Urban Complex, we detected a pattern of mutual exclusivity, or near-exclusivity, of activities at satellites.

A considerable degree of concentration of activities (especially, iron working, various styles of fishing, hunting aquatic mammals and snakes, weaving) continues to be the best explanation for the nonuniform, nonrandom distribution of surface and stratified artifacts in the Jenne-jeno Urban Complex. What does this clustering mean and what does this landscape say, potentially, about the distribution of power and authority within the larger community?

Some three and a half decades of research in the Jenne region allows us to say several things, with considerable confidence, about how this society was structured. First, clustering appears to have been a solution to the problem of how different specialist corporations might maintain and display their distinct identities, while at the same time having immediate access to other providers of needed goods and services and access to those to whom they themselves provide materials (Trigger 1972). One needs at the same time to answer the question: "Who monitors or controls the exchange of those manufactures and services?" An older theory of the nature of cities would have answered: "the king and his administration, backed up by force, of course (McIntosh 1999)." However, in the case of the Jenne-jeno Urban Cluster, we appear to have an exchange system that functioned organically through the relations of reciprocity forged among corporate groups. If corporate groups were defined unambiguously, and expectations and rules of reciprocity, including consequences if the rules were transgressed, the urban system would not have required a vertically hierarchical control structure – which in fact we do not see. Rather, corporate ownership of individual mounds by members of an occupationally defined/kin group is indicated by the archaeological data indicating near-exclusivity of occupational debris at each of the satellite sites.

Second, we have no hard evidence of a state-like, top-down, elite-driven political engine powering this kind of urbanism through time. We find no indications of kings, citadels, palaces, or indeed, any obvious elites. The political and economic organization of late first millennium B.C. and later urbanism in the Middle Niger seems heterarchical. That is, one identifies separate, if sometimes overlapping, domains of authority, all functioning in an interactive field, not a vertical hierarchy of kings and subjects and unidirectional flows of information.

Recent research reveals cities even earlier than Jenne-jeno and especially a "preurban" landscape in the northern reaches of the Middle Niger (Méma, Lakes Region and Timbuktu) (Park 2010; Togola 1996) and further north into the (Mauritanian and Malian Azawad) Sahara (MacDonald 2011) that was potentially several millennia in the making. This "preurban" landscape includes the creation of specialized sites

and activities in a regional economy (a self-organizing landscape in the language of complex systems (R. McIntosh 2005)). This landscape displayed great resilience in a challenging environment as the Sahara transformed from a well-watered savanna (with vast lakes) as late as the fourth millennium B.C. to its present condition by the late third or early second millennium.

Jennings, Jesse D.

C. Melvin Aikens
Department of Anthropology, University of Oregon, Eugene, OR, USA

Basic Biographical Information

Jesse D. Jennings was born in Oklahoma City July 7, 1909, and died at his home in Siletz, Oregon, on August 13, 1997. Married for some 60 years to Jane Chase Jennings, he left behind two sons, David and Herbert, and three grandchildren. The son of hard-scrabble dirt farmers, Jennings worked his way through Montezuma College in Hot Springs, New Mexico, graduating in 1929 and entering the University of Chicago graduate program the same year. There he supported himself by working on the campus grounds crew, as a hospital orderly, as a campus policeman, as an archaeological field worker, and ultimately as a holder of the Anthropology Department's coveted Ryerson Fellowship. After beginning with Robert Redfield and others in cultural anthropology, Jennings was drafted by department head Faye-Cooper Cole to serve in Chicago's archaeological field school, where he progressed rapidly into a supervisory role at sites in Illinois, the Southeastern USA, and beyond. This set him on the archaeological track that he followed the rest of his life (Jennings 1994). His Chicago Ph.D. dissertation, completed during WWII when he was serving as a Naval Officer in Newfoundland, was *The Site Kaminaljuyu and Its Contribution to Certain Problems of Mesoamerican Prehistory* (Jennings et al. 1946).

For some years after WW II, Jennings worked in the realm of archaeological stewardship for the US National Park Service in the American Southeast, Southwest, and Plains, during the early developmental phase of what we now call Cultural Resource Management (CRM) archaeology. In 1948, he joined the Department of Anthropology at the University of Utah, a position he held until his 1986 retirement at the rank of Distinguished Professor Emeritus. Jennings moved in

Jennings, Jesse D., Fig. 1 Jesse D. Jennings

his later years to the Oregon Coast, where he and his wife lived near their son Herb and his family and for many of these years taught a hugely popular spring seminar to worshipful graduate students of the University of Oregon Department of Anthropology (Fig. 1).

Major Accomplishments

Jennings distinguished himself early on, and throughout his highly active career, by a strong emphasis on strategically conceived and rigorously executed excavation, meticulously documented. His interpretive paradigm, applied over a long career to researches in the American Midwest and Southeast, Guatemala, the North American Plains, Southwest, Great Basin, and the Pacific Islands, was firmly based on ethnographic analogy and a direct historical approach that yielded him rich historical and ecological perspectives in all these settings.

Jennings' research at Danger Cave, a deep, dry grotto overlooking the final Pleistocene shoreline of Pluvial Lake Bonneville in far western Utah, was pathbreaking in its execution and dramatically rich in its conclusions and remains today his single greatest contribution to our understanding of North American prehistory (Jennings 1957). Making comparisons among the well-preserved material culture, flora, and fauna of Danger and other dry cave sites, and calling attention to many thoroughgoing congruencies between archaeological inventories and ethnographic accounts all across the region, Jennings described a Great Basin Desert Culture that was widespread, ancient, and stable in its fundamentals, maintaining the same basic adaptive patterns from about 10,000 years ago down to the nineteenth century.

The evidence and argument Jennings marshaled established a conception that will forever influence archaeologists' thinking about prehistoric hunter-gatherer cultural ecology in the American Desert West and similar situations elsewhere on the planet. Jennings' original presentation was broad and generalizing, but more closely focused applications of the same ecologically informed approaches are today also yielding important insights into more closely defined regional and local social economies across the same region.

Another major Jennings accomplishment was his focal role in creating the University of Utah Museum of Natural History, an effort that spanned in all more than 20 years. With the museum at last installed in the fine old campus library in 1973 and legislative funding assured for its continuance, he resigned as director, passing the job on to his longtime curator of exhibits. The museum has continued to flourish as a world-class research facility and contributor to public education, and as this is written, the University of Utah has just moved it into a new multimillion dollar building on its upper campus that magnificently expands and carries on Jennings' legacy.

In another aspect of his archaeological career, Jennings entered early into the writing and editing of synthetic archaeological volumes directed to peers and students (Jennings 1968, 1986). *Prehistoric Man in the New World* (1964), coedited with Edward Norbeck, and *Prehistory of North America* (1968), gave students and teachers two of the first textbook syntheses of the continent's archaeology, each continuing through three editions. In addition, *The Prehistory of Polynesia* (1978b) brought together under his

editorship synthetic essays by more than a dozen prominent students for a first-time summation of this vast area's long human history. His Glen Canyon (1966) and Prehistory of Utah and the Eastern Great Basin (1978a) brought together decades of work he conducted with generations of students.

Professional Awards and Honors

Editor of *American Antiquity* 1950–1954; Executive Board of the American Anthropological Association 1953–1956; Viking Medalist in Archaeology 1958; President, Society for American Archaeology 1959–1960; Vice-president and Section H Chairman, American Association for the Advancement of Science 1961, 1971. University of Utah Distinguished Professor 1974, Doctor of Science 1980. National Academy of Sciences 1977. Society for American Archaeology Distinguished Service Award, 1982. Distinguished Service Award, Society for Conservation Archaeology 1982. Plenary session speaker at the Society for American Archaeology 50th Anniversary Celebration, 1985. Jesse D. Jennings Prize for Excellence established by the Great Basin Anthropological Conference, 1990. A.V. Kidder Medal for Achievement in American Archaeology 1995.

Jericho Archaeological Site

Ian Kuijt
Department of Anthropology, University of Notre Dame, Notre Dame, IN, USA

J

Introduction

The transition between foraging and food-producing economies from the Levantine Late Natufian through to the Pottery Neolithic, at times envisioned by researchers as the period of *Neolithic Revolution,* is widely recognized as representing a crucial threshold in human prehistory. As seen with the excavations of Jericho, it is this period that we see profound changes in subsistence practices and economy, the emergence of the first villages, explosive population growth who settle down in these villages occupied on a year-round basis, and the reorganization of the processes and structures by which human social interactions occurred. This is most noticeable with the development of large community structures, such as the large Neolithic tower of Jericho excavated by K. Kenyon, and densely packed villages of rectangular mud brick residential buildings that came to characterize residential architecture since this point.

Definition

Tell el-Sultan, better known as the ancient site of Jericho, is situated in the Palestinian Autonomous

Authority, north of Wadi el-Mafjar on a moderately sloping plain formed by the Late Pleistocene Lisan Lake. Rising as a mound some 26–39 ft. (8–12 m) above the current landscape, the site of Jericho covers an area of at least 30,000 square yards (25,000 m^2) and is oval shaped, with its long axis oriented along a north-south line.

Key Issues/Current Debates/Future Directions/Examples

As a historical, biblical, and archaeological location, the settlement of Jericho provides insight into the appearance of the world's first villages in the Neolithic period, development of early Neolithic agriculture, the forager-farming transition of the Ancient Near East more generally, and the emergence of Bronze Age urbanism. Originally intrigued by the biblical tale of the walls of Jericho, many early archaeologists undertook biblically oriented excavations at Jericho. The earliest of these archaeologists was C. Warren, who excavated a series of deep, and remarkably unsafe, shafts into the mound in 1873. Following this, E. Sellin and C. Watzinger (1907–1908) opened up a series of trenches and were followed by the extensive excavations of J. Garstang (1930–1936). Focusing on the Early and Middle Bronze Age occupation, these researchers demonstrated that in the Bronze Age, Jericho was enclosed by a defensive wall system with a number of elongated rectangular towers. Jericho appears to have been continually occupied into the Middle Bronze Age, indicated by the extensive cemetery, with vertical shaft tombs and underground burial chambers. In the Middle Bronze Age, the town was expanded with the construction of glacis defensive fortifications. The elaborate burial offerings placed in some of the tombs of this period may reflect the emergence of local rulers. After destruction in the Late Bronze Age, Jericho no longer served as an urban center.

The early excavations at Jericho also revealed something totally unexpected: evidence for a Neolithic preagricultural village as well as preagricultural settlement of what we now know to be sedentary people living on wild plants and animals. Sellin and Watzinger and, later, Garstang uncovered remains of an earlier Neolithic settlement. Intrigued by these materials, Dame K. M. Kenyon undertook large-scale excavations of the prepottery Neolithic occupation at Jericho from 1952 to 1958 (Kenyon 1957, 1981). Kenyon's excavations demonstrated that Jericho was originally founded by sedentary foragers/collectors in the Natufian period (12,800–10,500 BP), living in large semi-subterranean oval stone structures, although it is unclear how extensive this occupation was. With the introduction of domesticated plants in the Pre-Pottery Neolithic A period (PPNA) (c. 11,700–10,500 cal. BP), Jericho mushroomed into a large regional agricultural community, covering an area of some 300 square yards (25,000 m^2). Villagers, like those of the nearby sites of Netiv Hagdud and Gilgal I, lived year-round in roofed, oval semi-subterranean dwellings and engaged in long-distance trading of Anatolian obsidian and shells from the Mediterranean and the Red Sea (Kuijt & Goring-Morris 2002). Living on domesticated and wild plant crops as well as hunting of wild game, adult individuals were buried in single graves, frequently with their cranium later removed to secondary locations.

Excavations at Jericho illustrated that this early Neolithic communities consisted of several hundred people, with systems of food storage and with sufficient labor to construct large community facilities. Kenyon's excavations of the PPNA layers at Jericho uncovered a spectacular large circular stone tower situated just inside of a 12-ft-high (3.6-m-high) perimeter wall (Fig. 1). Made of field stones, the tower was 28 ft. (8.5 m) in diameter, preserved to a height of 26.5 ft. (8 m), and had an internal staircase (Fig. 2). Kenyon argued that the tower and walls comprised an early defensive system. O. Bar-Yosef (1986) has questioned this view, arguing that the tower and perimeter wall served as a water diversion system to protect the PPNA occupants from winter floods. It is also possible that the western wall, which does not totally surround Jericho, facilitated the ponding of water so as to support agricultural and a waterfowl habitat. Elsewhere, Kuijt (1996) points out that at a later

Jericho Archaeological Site, Fig. 1 Pre-Pottery Neolithic A period tower of Jericho in trench I and squares FI and DI. Note the height of the tower, illustrated by excavators standing on top of and below the building, the square entrench to the staircase that goes to ground level, and the upper surface of the tower illustrate that the building was built in two periods and the outer surface was covered by mud. (From Kenyon 1981, Plate 5)

point, the tower was abandoned and the internal staircase was used for burials. It is puzzling to note, however, that even with the stairway being blocked off, the tower continued to have stood 5 or more meters above the ground surface and existed as a major building visible from some distance.

Over the last 20 years, research at several archaeological sites, such as Göbekli Tepe, Dhra', and WF 16, has illustrated that early villagers created corporate structures for food storage, community events, and perhaps seasonal feasts and mortuary ritual. There is active debate among researchers of how representative these structures were of life within Neolithic villages and how they would have been used as physical locations for human action. Excavation of Neolithic Jericho provides important insights into the question of the construction, use, and frequency of community buildings. For example, given that Kenyon opened up a surface area of less than 5% of the total surface area of Jericho, it is likely that the tower she identified and excavated was only one of many stone towers at Jericho. When she started excavations in 1952, the tower was invisible, and she had no idea what was below the ground surface. In light of the total surface area of the mound, it is entirely possible that there are four or more other Neolithic towers at Jericho.

Even if this is the only tower at Jericho, the construction of this building represents a major input of community labor that was far beyond the labor required to construct an individual home or the harvesting of plants. What this shows us, in brief, is that Jericho was not only a village of individual households who pooled labor for seasonal agricultural tasks: it was a village where household members cooperated in the construction of one or more large monumental buildings. This is all the more surprising when one realizes that these people were cultivating wild plants and hunting wild animals.

With the appearance of domesticated goat and sheep in the Pre-Pottery Neolithic B period (PPNB) (10,500–8700 cal. BP), significant changes occurred at Jericho and the rest of the Levant (Kuijt and Goring-Morris 2002). The village was expanded, with a greater number of residential buildings placed in relatively close proximity to each other and with the development of new ground and chipped stone technologies. The rectangular buildings were free standing and with fences, walls, and alleyways, would have created a complex village layout with single-story mud houses, courtyards, areas for stock, and homes for several hundred people. The PPNA tower and perimeter walls were abandoned, and PPNB villagers built rectangular (4 by 8 m) houses with painted red and white lime plaster floors (Kuijt 2000) (Fig. 3). Displaying continuity with earlier burial practices, PPNB villagers buried their dead in a wide range of locations within the settlement, and more specifically, in close proximity to their homes. Burial practices often included skull removal as part of an elaborate and highly complex system of defleshing and secondary interment of part of the

Jericho Archaeological Site, Fig. 2 Cross section of the Pre-Pottery Neolithic A period tower of Jericho. (From Kuijt 1996). Note how steep the stone stairway is and size of the tower

Jericho Archaeological Site, Fig. 3 Floor plan of partially preserved Pre-Pottery Neolithic B rectangular house of mud bricks of phase DI.xlii, showing reed foundation for plaster floor. The walls are made of hand-formed mud bricks that were stacked on top of each other to make an upright wall. (From Kenyon 1981, Plate 49b)

human body. Villagers often cached multiple human skulls beneath house floors and courtyard areas as well as individual skulls in a wider range of locations. Evidence of plastered human skulls, at times with inset saltwater shells for eyes and painted representations of hair and other facial features, clearly indicates the practice of a complex form of ancestor worship and the emergence of more complex social and ritual organizations. Villagers also developed new

ways of making chipped and ground stone tools, including the expanded use of pressure flaking to make new projectile point forms and the development of naviform core reduction to systematically create blanks for tools, and developed new ways of manufacturing grinding stones to facilitate the grinding of domesticated plants. Other important stone tool technologies involved the production of ground stone beads and other stone ornaments.

Kenyon's excavations of the Neolithic deposits clearly demonstrated that as one of the earliest and most important agricultural villages in the Jordan Valley, Jericho existed as a regional focus for the trade of exotic goods and agricultural products and possibly as a major location for ritual. As one of the, if not the most, extensively reported Neolithic sites in the southern Levant, our archaeological knowledge of Jericho serves as the foundation for understanding Neolithic cultural chronology, the emergence of agriculture, and the development of complex social organization in the Levantine Neolithic period.

Jerusalem (Hellenistic, Roman, and Late Antique), Archaeology of

Jon Seligman
Israel Antiquities Authority, Jerusalem, Israel

Introduction and Definition

Jerusalem القدس ירושלים (UTM: 31°47′N 35°13′E) sits at the heart of the highlands that run down the center of Palestine, bounded by the Syro-African Rift in the east and the limestone foothills of the Shephelah and the coastal plain to the west. A Mediterranean climate characterizes the Judaean hills, with wet cool winters strongly contrasting with hot very dry summers. The limited rainfall is augmented in Jerusalem by the existence of the prolific Gihon spring, whose difficult topographical location has long influenced the layout of the city. Jerusalem is spread over several hilly spurs, with the Kidron Valley on the east and the Hinnom Valley on the west. The city is divided by the Tyropoeon Valley with Mount Moriah on its eastern side.

Jerusalem has a history of six millennia, one of the most ancient continually settled cities in the world. Jerusalem has been Judaism's holiest city and spiritual center since the Iron Age; it is the site of the crucifixion and resurrection of Jesus Christ and the destination of the night flight (*Miraj*) of Mohammed. Mount Moriah, Jerusalem's acropolis, has formed the locus for religious tradition and

worship from the time of the Canaanite tribe of Jebus, through its role as the Temple Mount upon which two Jewish temples were both built and destroyed, as the site of the Roman temple of Jupiter Capitolinus, and as the location of the Noble Sanctuary (*el-Haram es-Sharif*) that contains the Dome of the Rock and the el-Aqsa Mosque, the last of which is outside the temporal framework of this entry. In addition to its place in the Old Testament, Jerusalem is important to Christians for its central place in the life of Jesus, especially for the events of the last week of his life. As a result of these events Jerusalem became the site of some of the most important shrines of Christianity.

Key Issues/Current Debates

The Hellenistic and Early Roman Periods: Second Temple Jerusalem

After Alexander the Great conquered the Persian Empire in 333–332 BCE, Jerusalem fell under Seleucid and Ptolemaic control and cultural influence. Disputes concerning the influence and imposition of Hellenism culminated in rebellion. As a result of the Maccabean revolt Jerusalem became the capital of the independent Hasmonean Kingdom for some hundred years, till a dynastic dispute led to Roman intervention and Judaea becoming an autonomous Hasmonean province. After the Romans appointed Herod as a client king around 19 BCE, he proved to be a dominant ruler whose work in the city influences the urban form of Jerusalem even today. Herod renovated the Temple, constructed major additions to the surrounding complex, and built new streets and walls. After Herod's death in 4 BCE, Judaea came under direct Roman rule and was governed by Roman procurators and Herod's successors until the Jewish population rebelled in 66 BCE. The future emperor Titus, leading the tenth Roman Legion Fretensis, reconquered and destroyed much of Jerusalem, including the Temple in 70 CE, an event commemorated on the Arch of Titus in Rome.

In the mid-second century BCE, the Hasmoneans encircled the Temple Mount, the City of David, Mount Zion, and the western hill with defensive walls that incorporated earlier walls of the Iron Age. The line of the new wall, known as the "First Wall," reached the Hippicus Tower, at the site of the medieval citadel. Sections of this wall have been excavated at a number of sites. In the first century BCE the "Second Wall" was built to enclose a new neighborhood between the Gennath Gate and the Antonia fortress, but it excluded Golgotha, the future site of the crucifixion, which was outside the city walls. In the first century CE King Agrippa enclosed Bezetha, an extramural suburb north of the city, within the "Third Wall," including the Psephinus Tower. The latter wall was only completed shortly before the Great Revolt (Fig. 1).

Dominating the Temple Mount was the Antonia fortress, which Herod constructed over an earlier Hasmonean fortress known as the Baris. The Antonia was a tetrapyrgion, a heavy rectangular building with four corner towers. On the opposite western edge of the city was a citadel incorporated within the walls and comprising three massive towers known as Hyppicus, Phasael, and Mariamne. To the south of the citadel was Herod's magnificent palace, for which Josephus provides detailed description of its opulent decoration. Its retaining walls have been exposed.

On the western hill, known as the Upper City, an elite residential quarter for the temple priests was set. Excavated palatial mansions consist of multistoried courtyard houses decorated with mosaic pavements and walls covered with colorful frescoes in Pompeiian style. Ubiquitous ritual baths (*miqve*) essential for Jewish ritual purification were found in all of these structures. A further mansion has been exposed in the lower Tyropoeon Valley; it shows that aristocratic dwellings were common within the city walls.

The growth of Jerusalem was guaranteed by the supply of water to the city through two sinuous aqueducts. These brought water from sources located 20 km to the south to the Tower pool near the citadel and the many cisterns cut below the Temple Mount. Additional spring water continued to fill the Siloam pool in the south, while runoff was collected in a pool beside the Antonia fortress from the Bezetha stream and in the nearby Bethesda pool.

The Temple prior to King Herod seems to have been relatively small. Thereafter, royal

Jerusalem (Hellenistic, Roman, and Late Antique), Archaeology of, Fig. 1 Jerusalem in the Hellenistic to early Roman periods during the Roman period (third century BCE–70 CE)

sponsorship of a massive new temenos, a raised platform and a magnificent temple glorified Herod's name and dominated the urban structure of the city. Herod's builders greatly increased the area of the mount by building huge and splendid supporting walls around a rectangular area of

15 ha. At the center, on the rock of Mount Moriah, stood the Temple itself. Although no exposed remains survive, it is described by Josephus Flavius as a large tri-cameral structure of white marble fronted by an altar. On the southern edge of the Temple Mount a huge administrative Royal Stoa was added. Archaeological finds that survived the Roman destruction of 70 CE have been located, including inscriptions, architectural details, and the outer temenos walls.

Below the western retaining wall of the Temple Mount was the main thoroughfare of Jerusalem. The road led from the Siloam Pool in the south and extended beneath the stairs over Robinson's Arch, which rose up to the Royal Stoa, and under Wilson's Arch, which carried traffic along a viaduct from the Upper City. South of the Temple Mount was a massive staircase that led to the Huldah Gates, the main entrance to the compound. Numerous public ritual baths in the vicinity were utilized by pilgrims prior to their ascent to the mount, while shops along the roads would have provided sacrificial animals, change for the temple tithe, food, and other services.

An extensive necropolis surrounded the city on all sides, including typical family burial chambers with loculi and secondary internment in stone ossuaries. Monumental aristocratic tombs with pyramidal roofs, colonnaded porches, and classical decoration suited to the Jewish religious requirements prohibiting images were found in the Kidron and Hinnom Valleys and to the north of the city. The most famous tombs are those named for Absalom, Bnei Hazir, and Queen Helena of Adiabene.

Roman Jerusalem: Aelia Capitolina

After the sacking of the city in 70 CE Jerusalem came under direct Roman rule. Close to the second Jewish revolt of 135 CE the Roman emperor Hadrian renamed the city Aelia Capitolina, laying it out as a Roman colony. Jews were excluded from the city. Major works included the establishment of a new urban plan, the founding of a large Roman legionary camp, and the building of a pagan temple on the site of the former Jewish temple (Fig. 2).

Considering the abundance of archaeological data and written sources concerning other periods, the dearth of both for the Roman city is striking. This requires us to rely greatly on the information imparted by sources of the sixth to seventh centuries that still express the layout of the Hadrianic founding. These portray a classical city divided into seven quarters, covering some 100 ha and populated by a number of major structures. The expulsion of Jerusalem's Jewish residents left the city lightly populated, a situation only partially rectified by the encouragement of settlement by veterans and Hellenic groups living in *Provincia Palaestina*.

The present shape and even road layout of the extant Old City of Jerusalem is a survival of the plan originally set out in the Roman colony. It accords with accepted planning concepts common to contemporary cities of the Roman East. In general, the city can be split into two sections. The southern part, which corresponds to the present Armenian and Jewish Quarters, was, in the view of many, the site of the camp of the Tenth Roman Legion Fretensis. The northern part was used for Jerusalem's civic and municipal buildings.

Controversy concerns the defense of the city, especially whether or not Jerusalem was surrounded by a wall or whether it relied on remains of fortifications left after the destruction of the Second Temple period city. Excavations do not provide evidence of a reconstructed wall for Jerusalem until the beginning of the fourth century when a wall raised for Jerusalem's defenses was established on a line that mostly continues till the present on the north and east. By contrast, recent studies have proposed moving the initial northern limit of the city to the line of the northern "Third Wall," until the late third to early fourth centuries.

The road network of the city was based on straight Roman streets crossing at right angles. Their exact paths were dictated by the hilly topography and the overshadowing remains of the Temple Mount left unscathed by Titus. At the northern extreme was a monumental gate that now forms the base of the Damascus Gate, with a dedicatory column to its south. Two colonnaded cardines stretched from the gate to the south, and they were crossed at their center by a *decumanus*.

Jerusalem (Hellenistic, Roman, and Late Antique), Archaeology of, Fig. 2 Aelia Capitolina during the Roman period (early fourth century CE) (After: Tsafrir 1999a. Map in back cover)

J

Sections of the western *cardo* have been uncovered east of the Holy Sepulchre, including columns of the arcade that flanked the street itself. The *cardo* was laid as far as the south-western hill, to the legionary camp, while the southern section of the *cardo* was only laid in the Byzantine period by Justinian, a conclusion challenged by those who give a Roman date for the entire street. Of the eastern *cardo* a large portion has been uncovered just south of the crossing with the *decumanus*.

The main streets would have led to four gates, of which only the northern has been excavated. The other gates stood in the general area of what are now known as the Jaffa, Lions, and Zion Gates.

The magnificent northern free standing triumphal arch of the Roman colony, possibly known as Porta Neapolitana, was built with the founding of the city. The remnants below the sixteenth century Damascus Gate have exposed a gate of three entrances flanked by two huge towers. Set over the entrances was the fragmentary inscription dedicated to the *decuriones* of the Colony Aelia Capitolina. Only with the construction of the northern city wall in the late third or early fourth centuries was this arch included in the city's defensive line. Similar triple triumphal arches were also built inside the city – near the forum (Ecce Homo), east of the Holy Sepulchre, and maybe even in the south of the city. Discovered north of the Damascus Gate on the road out of city were architectural elements of a possible further gate that may have been integrated into the northern wall on the line of the earlier "Third Wall."

A major development of the hydrological supply was the construction, or at least renovation, of the high level aqueduct. This aqueduct includes a 2.5 km section enclosed in a stone pipe siphon constructed by the Tenth Legion Fretensis. Furthermore, water collected from the Gihon spring entered the Siloam pool, which was now surrounded by colonnades on all sides.

After the taking of Jerusalem in 70 CE the Tenth Legion Fretensis was stationed in the city till its transfer by Diocletian at the end of the third century. According to a view held by most scholars the camp was located on the south-western hill, as indicated by the presence of many stamped tiles of the legion found in excavations in the area. The command of the legion was most probably garrisoned in the Herodian towers that were left standing by Titus.

The gateway to the legionary camp probably opened into the compound on the line of the present Christian Quarter Street, which probably bisected the camp through its center. However, the lack of permanent garrison structures, clear finds usually associated with legionary camps and obvious fortifications on the south-western hill have led some scholars to doubt the identification and to suggest alternative locations to the south of the Temple Mount.

The public amenities and civic structures of Jerusalem included two *fora* and a number of temples. The main *forum*, beside the corner of the western *cardo* and the *decumanus*, included a basilica and probably the Temple of Venus-Aphrodite or of Jupiter. The eastern forum was situated north of the Temple Mount. Its triumphal arch, known as the Ecce Homo, was placed on its western edge and spanned the eastern part of the *decumanus*.

A sculpted relief, associated by the excavators with the cult of Aesclepius-Serapis, was uncovered close to the Bethesda Pool. Furthermore, a temple dedicated to the Capitoline triad of Jupiter, Juno and Minerva together was possibly established on the Temple Mount, along with two statues of the emperor Hadrian. Some scholars prefer to identify this Capitolium with the temple located in the central forum, on the site that would later be occupied by the Holy Sepulchre.

Byzantine Jerusalem

In 326 CE Helena, the mother of Constantine identified the site of the burial of Christ under the Temple of Venus, instigating a renaissance for Jerusalem. At the instruction of Constantine the construction of a huge church began at the site.

Jerusalem would develop to become a major city of Christendom and, from 451 CE, the seat of an independent Patriarchate. Within the walls and in adjacent areas outside them a series of important Christian edifices and monastic establishments were built under the auspices of imperial sponsorship and private donation. Church building would continue throughout Byzantine rule, with a short hiatus between 361 to 363 CE when Julian the Apostate encouraged the rebuilding of the Temple by the Jews. The end of Byzantine rule was preceded by the brutal Persian incursion of 614 CE, though the reported damage does not seem to be mirrored in the archaeological evidence. The Umayyad occupation of 638 CE brought the city under Muslim rule. Even with the commissioning of the Dome of the Rock over Mt. Moriah and the al-Aqsa Mosque in the southern part of the Temple Mount, the city's Christian character would only slowly change over the coming two centuries (Fig. 3).

With the adoption of Christianity as the state religion the Capitoline triad ceased to be honored, a transformation commemorated by the use of the official name Aelia for the city until the mid-fourth century, at which point the name Jerusalem was once again typically used. In marked contrast to the previous era, the Byzantine period is served by a plethora of sources, especially by the writings of Church fathers and pilgrims' itineraries that provide detailed descriptions of the history and topography of the city.

Beside ecclesiastic construction there was also extensive municipal and civic expansion, opened by the rebuilding of the defensive wall probably during Constantine's reign. Residential quarters filled the intermural area of 120 ha, spilling beyond the wall to the north and west to include new monasteries and commercial structures. The influx of Christian pilgrims from many nations raised the population to around 50,000, speaking a variety of languages.

The Byzantine town plan, as represented on the Madaba mosaic map of the seventh century, preserves the layout of the Roman city. It shows Jerusalem to be surrounded by a wall, towers, and gates and to be dominated by the Roman St. Stephens (Damascus) Gate on the north, the two colonnaded cardines, the *decumanus*, and the new monuments that defined the city's Christian topography – the Church of the Holy Sepulchre, the Zion Church, and the Nea. The complete refortification of Jerusalem has been illuminated by numerous excavations around the circumference that included the renovation of earlier walls. Sections of the wall have been found in the Ophel, the Kidron Valley on the eastern slope of the City of David, around the Siloam pool, across the Tyropoeon Valley, on the western side of the city in the Armenian Garden and the Citadel, and then along the line of the northern wall of the Old City including the Damascus Gate. Wall sections associated with Empress Eudocia were also found along the southern slope of Mount Zion. The date of the fortification has been debated, with some dating it to the late third to early fourth century, and others proposing a date a century later.

The continuity of the urban structure of Jerusalem from the previous period has already been emphasized. With the abandonment of the legionary camp, the south-western hill was ready for development. The western *cardo* was extended as a magnificent colonnaded street to Mount Zion, probably as part of Justinian's plan to connect the Holy Sepulchre with his newly constructed Nea Church. The eastern *cardo* was also renovated, and its southern sections dating to this period continued down to the Siloam Pool. New routes more closely following the topography in a haphazard organic development rather than the conventions of Roman planning, which had previously been used, were created. During the sixth century, both public and private buildings began to encroach onto open spaces, including the *fora* and even onto the public pavements that flanked the cardines. This encroachment reached its zenith in the following periods.

Numerous private dwellings, many of them prestige residences, were uncovered in the City of David and on the slopes of the Tyropoeon Valley flanking the streets down to the Siloam

Jerusalem (Hellenistic, Roman, and Late Antique), Archaeology of, Fig. 3 Jerusalem during the Byzantine period (After: Tsafrir 1999b. Map in back cover)

Pool; in the Ophel, where large houses surrounding courtyards were accompanied by a substantial bathhouse west of Robinson's Arch; on the southwestern hill; and on Mount Zion. A characteristic difference between the Byzantine city and the Roman city was the deterioration of functional divisions, whereby public and private zonal separation disappeared. Homes, commercial buildings, civic monuments, and religious institutions could now be found side-by-side.

Byzantine Jerusalem was dominated by ecclesiastical institutions representing both the events of the life of Christ and the numerous national communities that found their home in the city. Both the earliest and the most important church in Jerusalem was the Church of the Holy Sepulchre, built in the early fourth century on the instruction of Constantine, at the site identified by Eusebius as the locus of the crucifixion, burial, and resurrection of Jesus Christ. The new structure, built in place of a temple in the main *forum*, was entered from the *cardo* through an atrium that integrated part of the entrance of the dismantled Roman basilica and temple. One then proceeded through a large basilical church or *martyrium* of four aisles and a wide central nave with a single apse facing westward toward the tomb, a *triportico* that included the rock of Golgotha, and a rotunda or *Anastasis* with three apses that enclosed Jesus' tomb in an aedicule at its center. Ancillary buildings, including a baptistery, monasteries, and other structures were certainly located beside the church.

Mount Zion was home to the Church of Holy Zion built in 340 CE, and repaired in the fifth century. The church was built on the site identified with the Last Supper, the gathering of Jesus with the Apostles, the dormition of the Virgin Mary, and other traditions. The church was located on the southern end of the road that had bisected the legionary camp and was used as a processional way between the Holy Sepulchre and Mt. Zion. The limited remains enable a reconstruction of a basilica with four aisles and a nave leading to one of three external apses.

Emperor Justinian's huge Nea Church of Mary Theotokus was dedicated in 543 CE on Mount Zion. This church was the second largest basilica in Jerusalem, occupying a topographically dominant position above huge terraced retaining walls that enclosed a massive underground reservoir. In the south of the city, a church consecrated in the fifth century, probably by the empress Eudocia, opened to the colonnaded Siloam pool dedicated to the miracles of Christ at the pool (John 9: 1–12).

Other churches of note within the walls were the trefoil Church of John the Baptist, the Church of Saint Mary of the Probatica, which was set above the dividing wall between the two pools previously associated with the Roman cult of Aesclepius-Serapis, and the church of Peter in Gallicantu on the southern slope of Mt. Zion.

We learn of the monasteries of Jerusalem both from the written sources and from the results of excavations. Jerusalem was home to many monastic foundations, many of them connected to national groups and to the many *conoebia* and *laura* that populated the Judaean desert.

The status of the Temple Mount during the Byzantine period is a matter of some controversy. Certainly its very physical presence was the dominant feature of Jerusalem's topography, both structurally and as an important focus of the urban plan. Some insist that the whole area was left undeveloped as a testimony to Christianity's triumph over Jewish ambitions to rebuild the temple, while others suggest limited construction on the Mount. Without excavation these proposals remain speculative.

The peaceful conditions and safety enjoyed under Byzantine rule created public confidence to establish rich monastic institutions, residential neighborhoods, commercial districts, and cemeteries outside the city walls. These were concentrated to the west, north, and east of Jerusalem, especially along the routes out of the gates, and at sites of pilgrimage. To the west of the city a bathhouse fed from water from the high aqueduct was located on a commercial street of shops on the road leading directly out from the Porta David (Jaffa Gate).

North of the Damascus gate a closely clustered group of monasteries was discovered around the basilical church dedicated by Eudocia to St. Stephen in 460 CE. Nearby further monasteries were established, including institutions associated with the Armenian church. Among the

many ecclesiastical institutions in the area of the Mount of Olives were those excavated at Gethsemane, those at the Tomb of the Virgin Mary, Viri Galilaei, Dominus Flevit, the circular Church of the Ascension built in the fourth century, and the Eleona Church built by Constantine.

The area surrounding the city, which had served as the necropolis of Jerusalem since earliest times, continued to be utilized for burial, at times though the reuse of burial caves cut in earlier periods. The cultural transition from the Roman to Christian period is not illuminated by clear markers, beyond the initial entry of Christian symbols that would later unambiguously denote the change into the Byzantine period. A number of burial types have been identified. These include cist burials, shafts leading to a sealed chamber, a stepped dromus before a burial chamber with arcosolia cut into the rock, elaborate catacombs, and rows of graves in the crypts of the monasteries.

Introduction

The study of Jewish communities that settled in the former Spanish colonies, particularly in New Spain, Mexico, has been insufficiently approached from an archeological perspective. This field has been the endeavor of historians who have researched the topic extensively, particularly in Mexico, Peru, and Argentina (e.g., Alberro 2013; Chuchiak 2012; Greenleaf 1995; Jiménez Rueda 1946; Hordes 1982; Krause 1987; Liebman 1963, 1964, 1967, 1971, 1973; Shaposchnik 2015; Silverblatt 2000; Toro 1993; Uchmany 1985, 1992; Wiznitzer 1962; Zárate Miguel 1986). In contrast to Spain where *juderías (*quarters inhabited by Jewish communities) have been excavated, in other regions of Latin America, especially in Mexico, there is a lack of awareness of the potential of these areas within major urban centers. This could be because Jewish individuals, who arrived from Spain and Portugal to New Spain and other Spanish colonies during the sixteenth and seventeenth century, were Sephardi Jews converted to Catholicism, they were new Christians, crypto-Jews, or secret Jews (Liebman 1967; Wiznitzer 1962). This meant that although they had converted publicly to Christianity, many practiced Judaism in secrecy. As a result of this, there is a lack of material culture that was used for the outward display of their religious practices during that period. Thus, there are no public sites where synagogues and *juderías* were located, except in Brazil. Examples drawn from archaeological excavations of medieval sites with Jewish occupation in the Iberian Peninsula may shed light on the kind of material culture that was used by Jewish communities in the New World. Also, the data drawn from historical sources on the Inquisition from the sixteenth to the seventeenth century have the potential to inform on this. While the identification of settlements from the sixteenth to the early-nineteenth centuries may be problematic, those pertaining to the late nineteenth and early twentieth centuries can be easily located. This is so because the communities that arrived as part of late migrations displayed their cultural and religious identities publicly, in contrast to earlier ones. Consequently, in Mexico City and former Spanish colonies, the sites of synagogues are known as well as the streets where the modern *juderías* are situated.

Definition

The archaeology of Jewish communities is a research field that encompasses the material remains of Spaniards and Portuguese with a Jewish background that migrated to the New World, particularly to Mexico and South America, during the sixteenth, seventeenth, and eighteenth centuries. These individuals were known as New Christians that practiced Judaism in secret, away from the eyes of the public and religious authorities. This field of study extends to Sephardi and Ashkenazi Jewish communities that settled in Mexico, Brazil, Peru, and Argentina during the late-nineteenth and twentieth centuries.

Key Issues/Current Debates/Future Directions/Examples

The arrival of Sephardi Jews to the New World Spanish colonies occurred after their expulsion from Spain and Portugal in 1492 and 1497, respectively. Some of them like Luis de Torres accompanied Columbus on his first voyage. Others like Hernando Alonso, a ship carpenter who was put on trial and burned at the stake

accused of practicing Judaism, collaborated with Cortés in the conquest of Mexico in 1521 (Jiménez Rueda 1946, 85; Liebman 1963). Luis de Carvajal, *El Conquistador*, defeated the English in a naval battle off the coast of New Spain in 1568. In 1579 he received a royal contract from King Philip II awarding him with the governorship of the New Kingdom of Nuevo León in the north of Mexico (Liebman 1967, 20, 26; Toro 1993, XXII–XXIII). Others that were accused of practicing Judaism, like Gonzalo Gomez, settled in Michoacán (Toro 1993), and still others, in mining regions like Pachuca, Taxco, and Zacatecas Mexico (see Jiménez Rueda 1946; Toro 1993) (Fig. 1). In 1522 and 1523, Charles V signed a document that forbade Jews, Moors, and New Christians and their descendants from traveling to the Indies. Those who were found residing in the Spanish colonies were to be sent back to Spain. If they did not comply with this edict, they were deported, and their properties were confiscated. The decree lasted until September 16, 1802. Despite these prohibitions, many Jews settled in New Spain decades later (Greenleaf 1992, 108–109; Jiménez Rueda 1946, 83–84; Liebman 1963, 96; Toro 1993; Uchmany 1985, 265). By 1590 a Sephardi Jewish community was well established in Mexico City. It is estimated that by the mid-seventeenth century of the total population of

Jewish People in Mexico and South America, Archaeology of, Fig. 1 Geographical locations mentioned in the text

20,000 in New Spain, 2000 to 3000 were Jews (Liebman 1963, 100).

The Material Culture of Ritual and Religion

Emphasis should be made on the study of objects related to religious practices. That is because the Jews that migrated to places like New Spain, Mexico, in the sixteenth and seventeenth centuries cherished Spanish language, customs, and Spain itself. They were probably strongly acculturated into Spanish culture (Liebman 1967). Therefore, the material culture they used in the colonial environment may not have been significantly different from that employed by Old Christians in daily life, namely tin-glazed tableware like majolica. Because Spanish and Portuguese Jews that settled in the New World continued to practice their religion, one important source for the identification of these cultural groups corresponds to ritual objects. This kind of material culture may find parallels to that found in Spain even when Judaism in New Spain was practiced in the private realm away from the eyes of the public. There was no public display of spaces where Jews gathered like synagogues and *juderías,* and these were concealed. But the existence of secret rituals and synagogues, at least in Mexico City, has come to be known through historiographical studies on Jews put on trial by the Inquisition (see Jiménez Rueda 1946; Toro 1993; Liebman 1967). Therefore, it is expected to find some material culture related to such practices. Among the sources that could enable the identification of this kind of material culture are the findings of distinctive objects associated with rituality in Spanish *juderías.* The examples drawn from the excavations at *juderías* in the Iberian Peninsula suggest the use of ritual objects that distinguished Judaic groups from others like Christians and Muslims. These correspond to glazed clay candleholders known as *hanukiya* (see Pujante Martínez and Gallardo Carrillo 2004) (Fig. 2a). In Mexico City, a variety of glazed clay candleholders have been recovered in archaeological excavations and a particular type finds some similarities with the *hanukiya* from Spain and requires further consideration. The body of these candleholders is open with curved walls. The base has a geometrical design in the shape of a six or an eight- point star (López Palacios 1998, 475) (Fig. 2b).

A similar situation occurred in Argentina, where Jews were legally forbidden from settling but in practice were tolerated and hidden mainly because they held significant roles within Spanish society, e.g., merchants, bakers, and shoemakers. Evidence of this presence was found at an eighteenth-century house in the city center of Buenos Aires where architectural restoration revealed a ceramic floor preserved under a later mosaic one. On the internal surface of one of the

Jewish People in Mexico and South America, Archaeology of, Fig. 2 (**a**) Hanukiya found at the *judería* of León. (Re-drawn from Pujante Martínez and Gallardo Carrillo 2004). (**b**) Candleholder recovered at archaeological excavations in Mexico City. (Re-drawn from López Palacios 1998)

ceramic tiles an incised Star of David was identified (Shávelzon 2013).

Brazil constitutes a separate example from the Spanish colonies. After 1637, with the Dutch occupation of the northern portion of the Portuguese colony of Brazil, Jewish people in Recife were allowed to construct the first synagogue in America, the *Kahal Zur Israel*, which functioned until 1645. The synagogue was only known through documentary sources, but archaeological research at the site where it was presumably located was able to verify its existence. The most significant element that was found in the excavations was the *Mikvé*, a water pool for ritual baths (Albuquerque and Lucena 2003).

Another source of information concerning the material culture of Jewish communities in Mexico, and that is most useful for archaeological research, can be found in historic and historiographical sources (e.g., Alberro 2013; Greenleaf 1995; Jiménez Rueda 1946, 86–87; Toro 1993). These include Inquisitorial documents, trials, testimonies, testaments, and inventories. They provide unique insights into Jewish life and material culture during the Colonial period in Mexico, for example, avoiding pork, rabbit, hare, and fish without scales in their meals. The preference for particular meats like lamb and beef cut with a sharp knife in a specific fashion known as *Shechita*, *landrecilla*, or porging, and that had to be eaten whole, without breaking any bones, and the fondness for certain poultry; celebrating the candle feast, that is, Hanukah, where candles were burnt one after the other each day of the week; burying the dead covered in a shroud with a pillow under their heads and gold or a*ljófar* coins, that is with a symbolic value, in their mouths or under the body, among many other ritual practices (Jiménez Rueda 1946, 86–87, 93, 101; Toro 1993, 256; Liebman 1967, 45). It is worth considering these as they may have left a trace in the archaeological record.

Memorial Sites

The identification of places associated with Jewish occupation within the former Spanish colonies is essential to reconstruct a landscape of memorial sites. More often than not, these spaces are considered as pivotal within the Catholic landscape (Fig. 3). They are seldom thought of as commemorative places of other religious communities. However, these are sites where Jews were put on trial, incarcerated, tortured, and sometimes executed during the sixteenth and seventeenth centuries, particularly in Mexico an Peru (see below). These sites in Mexico City include the Colegio de Tlatelolco where Jews like Hernando de Alonso and Gonzalo de Morales were trialed and burned at the stake in 1528 (Greenleaf 1992, 108–110). Jewish writer and mystic Luis de Carvajal *El Mozo* also known as *El Alumbrado* was incarcerated also at Tlatelolco before dying by strangulation. His body was burned at the stake alongside eight other Jews (Liebman 1967, 32–33). Also, the Inquisition Palace, the plaza and former convent of Santo Domingo, the Cathedral, the Plaza Mayor, and the Plaza of the church of Saint Hipólito are symbolic (Fig. 3). The Inquisition Palace is probably one of the most emblematic buildings associated with a Jewish presence. There exists a vast corpus of information on the accusations made against Jews and on their imprisonment in the secret chambers, trials, and torments administered on behalf of the Inquisition. It was created in Mexico and in Peru by royal decree in 1569 (Medina 2010, 41). Before its legal foundation, many prisoners were put on trial and tortured in the *Palacio Arzobispal,* the palace of the archbishop of Mexico City. With the arrival of Moya de los Ríos to Mexico City in 1571, the Inquisition initiated its functions at the monastery of Santo Domingo. A few months later, it moved to the place where the actual building still stands and remained there until its suppression in 1819 by the court of Cadiz (Medina 2010). A revision on the Jews that were trialed by this institution can be found in Toro (1993), Liebman (1967), Greenleaf (1995), and Medina (2010).

The administration of sentences in New Spain was under the charge of the Inquisition during the *auto de fé.* This literally means "act of faith," a royal and public ceremony, during which the Inquisition tried and punished those that violated the Catholic faith. Depending on the sentence, the religious authorities handed over the prisoners to secular authorities to receive punishment. The auto

Jewish People in Mexico and South America, Archaeology of, Fig. 3 Landscape of memorial sites in Mexico City. Map of the old quarter of Mexico City with commemoration sites and residence areas mentioned in the text

was generally celebrated on a Sunday or on a particular feast that could bring together a large audience (Cañeque 1996, 322; Liebman 1973, 19). In the same fashion as the Peninsular *auto de fé*, this ceremony intended to "announce punishment across the world" and "extinguish heresy" (Ruíz de Zepeda Martínez 1659), and defend this religion and culture against heretics (Alberro 2013, 77–78). The great *autos* were sometimes celebrated at the Cathedral (Jiménez Rueda 1946 104–105), or more generally at the plaza mayor of Mexico City (Ruíz de Zepeda Martínez 1659) (Fig. 3). Smaller ones known as *autillos* were held within the private realm and inside the church of Santo Domingo or at the Inquisition Tribunal (Alberro 2013, 78; Cañeque 1996, 322; Liebman 1973, 19).

During the first stage, the penitents were covered with *Sambenitos,* a penitential garment, at the Inquisition Palace. From its main entrance, they solemnly marched through the streets of Mexico City towards the Cathedral, where their sentences were often read, and great *autos* were occasionally held (Jiménez Rueda 1946, 104–105), or to the plaza mayor of Mexico City. The convicted heretics made their abjurations and retractions and some were absolved and vindicated. The condemned ones walked a final procession with the effigies of others that were dead or absent and the bones of those that were taken by the secular authorities, postmortem, to the burning place or *quemadero* (Cañeque 1996, 321; Jiménez Rueda 1946, 104–105) at the market plaza of the church of Saint Hipólito (Fig. 3). At the *quemadero*, during the *auto* of 1649, for example, accused Jews suffered the garrote. Their dead bodies consumed by the flames, and the bones of the deceased ones, were turned to ashes (Jiménez Rueda 1946, 117).

In the *autos* that took place during the late sixteenth and seventeenth centuries in Mexico (e.g., 1590, 1596, 1601, 1603, and 1649), many Jews were put on trial. In 1601, of 123 tried persons, 39 were Jews. In the great *auto* of 1649, 14 relapsed Judaizers were put on trial and strangled with the garrote. One of them was burned alive at the stake (Wiznitzer 1962, 222–225).

During the great *auto* of 1659 in Mexico City, those condemned to die at the stake were mainly Blacks and mulattoes, the rest of them were whites accused of practicing Judaism. Among the 130 Jews that were relaxed to the secular authorities, 29 were burnt alive (Cañeque 1996, 332). As a consequence of punishment, many of their properties were confiscated and resulted in financial ruin. Others were imprisoned or forced to serve time at the galleys in ships. Still, others died at the garrote, and their bodies were burned afterward. The punishment for convicted Jews that had fled Mexico or had died before the *auto* was the trial or burning of their effigy and the exhumation and burning of their remains (Wiznitzer 1962, 222–225). The final resting place of these bodily remains is unknown, and further research on this specific topic is much needed. The few references made to Jewish burial sites are mentioned by Jiménez Rueda (1946, 123) concerning Juana de Enríquez; she was buried in 1646 in Jewish fashion at the Convent of El Carmen in San Angel, Mexico City, and was later disinterred by the Inquisition. For cases in Peru during the seventeenth century, see Silverblatt (2000) and Shaposchnik (2015), e.g., the trial of Rodrigo Váez Pererira who was accused of practicing Judaism in secret and died at the stake. For the case of bachelor Francisco Madlonado de Silva who was taken from Chile to the secret prisons of the Holy Inquisition in Lima and later died at the stake in 1639, see Günter Böhm (1984).

Memorial sites also comprise domestic spaces lived by Jewish families. Even when the identification of such places is difficult due to the scarcity of available archaeological data, some hints can be drawn from historiographical sources. An example of these is the house of de Almeida in Mexico City, who was a former inhabitant of a *judería* in Portugal and had traveled to New Spain in 1546. The Jewish community frequented his house during feasts (Jiménez Rueda 1946, 95) (Fig. 3). There are also a few references made to the house of the brothers of Luis de Carvajal, *el Mozo*. Around 1589, it was located adjacent to the Colegio de Niñas in Mexico City (Fig. 3). The Carvajal family had a second property in the portal of the *acequia* or water ditch next to the plaza, assuming that it refers to the former Plaza del Volador (Toro 1993, 257) (Fig. 3). Moreover, the house of Antonio Machado, an accused Judaizer, who was held amongst the Jewish community of New Spain as a great rabbi, was located next to the hermitage of Saint Sebastian in Mexico City (Fig. 3). His house was a sort of synagogue where Jews met secretly to pray, sing, and read the Bible (Jiménez Rueda 1946, 87). In Buenos Aires, the house of Tellechea in the city center (see above Shávelzon 2013) is a memorial site. Many other Jewish residences may have existed in the same area of Buenos Aires and may have functioned as familiar synagogues.

Other sites pertain to the late nineteenth and twentieth centuries. These are associated with a second significant Jewish migration that took place between the Mexican Independence in 1821 and the Revolution of 1910 and subsequently from 1910 until 1930 when a Jewish community was publicly established in Mexico City (Krause 1987, 31–33; Zárate Miguel 1986, 77). There were mainly bankers, physicians, soldiers, and merchants that traveled from Germany, Austria, England, France, Russia, Poland, Turkey, and Syria. Even though these immigrants are not the descendants of the Sephardi groups that arrived during the Colonial period, they can be considered as the founders of the contemporary Mexican Jewish community (Krause 1987, 31–33, 43). These groups at first established their synagogues and commercial depots in the historical quarter of Mexico City, and the former locations of these are still known today. An example of this is the synagogue Monte Sinai, located in the street of Justo Sierra and the second one in Jesús María. Around the synagogues, a *judería* grew with its kosher butcheries and bakeries in the modern streets of Guatemala, Justo Sierra, Loreto, and Academia (Fig. 3). In Peru, Jews from Central and Eastern Europe, Morocco, Turkey, and Siria immigrated during the late-nineteenth century. Many Sephardic Jews from North Africa and the Middle East arrived to the Peruvian Amazonia during the nineteenth century driven by the rubber market. They established at Iquitos and created a Jewish-mestizo culture. In the twentieth century, more Jews arrived to Peru from Russia, Poland,

and Romania, and also from Palestine and Egypt (Cadenas Erazo 2010), and have established synagogues and cemeteries especially in Lima.

Future Research

To approach the archaeological study of Jewish communities, an interdisciplinary approach is necessary. It can be achieved by combining the analysis of primary sources, cartographic ones, and excavated material culture, particularly the one associated with religious practices. Also, awareness of architectural features and religious insignia is required to identify domestic and ritual spaces related to Jewish religion. Other types of material culture that could be useful for this purpose correspond to zooarchaeological remains. Eating manners may provide a handy source for the identification of particular cultural and dietary practices and prohibitions, like the consumption of pork and certain meat-cuts. Thus, it is necessary to search for these elements in the archaeological samples. These could allow explore acculturation processes, patterns of consumption, and the strategies set forth by these cultural groups to display their identities in the private realm.

Li Ji [Li Chi]

Alice Yu Cheng
University of Oxford, Oxford, UK

Basic Biographical Information

Li Chi or Li Ji 李济 (1896–1979) was born in Hubei but grew up partly in Beijing. After finishing his undergraduate program at Tsinghua Academy, he went to the USA to pursue a master's degree in psychology and sociology at Clark University. In 1923, studying under E.A. Hooton, Alfred M. Tozzer, and Roland B. Dixon, he earned a doctorate in Anthropology from Harvard University. He then returned to China and taught at Nankai (1923–1924) and Tsinghua (1925–1928) universities. From 1925 to 1926, as the first Chinese excavator, he participated in the joint effort of Tsinghua Institute and the Freer Gallery of Art, Washington D.C., and excavated the Neolithic Yangshao 仰韶Culture site at Xi Yin 西阴, Shanxi 山西. In 1928, he directed the first archaeological section at the Institute of History and Philology, Academia Sinica. From 1928 to 1937, Li conducted 15 seasons of excavations at the Shang 商sites in Anyang 安阳and the Neolithic sites in Longshan 龙山, using modern and scientific archaeological approaches. He was forced to terminate his fieldwork in 1937 when the Sino-Japanese War broke out. In 1949, as the government of Chiang Kai-shek (ROC) exiled to Taiwan, he relocated with the Institute of History and Philology to Taipei and became the head of the Institute in 1955. He also founded and led the Department of Anthropology and Archaeology at the National Taiwan University. Subsequently, Li served as chairman of the Chinese Council for East Asian Studies, a subsidiary organization of the Harvard-Yenching Institute, and as board member of the National Science Council of the Republic of China. Throughout his career, Li trained the next generation of archaeologists, including K.C. Chang 张光直, Xia Nai夏鼐, and Guo Baojun 郭宝均. He advocated international collaborations, particularly those between the USA and the ROC. He paid numerous visits to the USA, Europe, and Australia to facilitate and promote scholarly exchanges.

Major Accomplishments

Li Chi was a key figure in shaping and advancing modern Chinese archaeology. His research on the Neolithic cultures adds a prehistoric extension to the studies of ancient Chinese civilization. Excavating and publishing the materials from the late Shang site in Anyang, Li marked a milestone in the understanding of the first dynasty with written records in ancient China. During his excavation, tombs in the hundreds, bronze vessels, skeletons, and oracle bones were uncovered and carefully documented. In addition, excavating Anyang, Li applied and demonstrated modern archaeological concepts and methods, leaving a lasting impact on Chinese archaeology. For example, he

emphasized the importance of the context in which the objects are found and of stratigraphy in establishing the chronology of the site.

Another major accomplishment of Li is that he designed a systematic classification of artifacts, departing from the methods used in Chinese antiquarianism that depends heavily on classical texts. Li classified the bronze vessels and pottery solely based on their formal features. Categories such as "flat-base" and "round-base" vessels, "tripods," and "ring-footed" vessels were established. Subcategories focusing on the detailed visual elements such as the decorative motifs were made for further distinctions.

Li Chi wrote extensively on Chinese archaeology, particularly on topics related to the Anyang materials. For example, Li published three lectures he gave in the USA in 1954–1955 in *The Beginnings of Chinese Civilization* (1957). In the book, he introduces the known prehistory as background to the emergence of the Shang civilization and examines the numerous cultural streams that may have contributed to the formation of the Shang culture. He also compares the Shang bronze vessels with artifacts from other cultures in the Near East and Asia, suggesting that certain similarities in the formal features indicate possible contacts. He provides chemical analyses and detailed account of the excavated objects from Anyang, particularly Xiaotun and Houjiazhuang, including the bronze vessels and dagger-axes [*ge* 戈]. Observing the formal characteristics of these objects, he defines the four cultural stages at Xiaotun.

Supplementing to his findings, in *Anyang* (1977a), Li chronicles and describes not only the archaeological but also the administrative activities relevant to his excavations. He summarizes and further interprets the published data of Anyang. He elaborates on the reasons as well as the historical circumstances under which he conducted these excavations. He also gives an account on the fieldworks of his colleagues, situating their scholarship in the broader development of modern Chinese archaeology.

With his training in the USA and field experiences in China, Li Chi successfully managed to integrate the academic approaches and research results from both sides. His writings, many of which in or translated into English, made the understanding of ancient China and the archaeological findings accessible to a broader group of audience, especially in the English-speaking world. His perspectives and analysis of the Shang culture also facilitate comparative studies in world archaeology.

Jiahu: Agriculture and Domestication

Sheahan Bestel
Institute of Archaeology, Chinese Academy of Social Sciences, Beijing, China

Introduction

The Jiahu site is located in the Huai River Valley, Wuyang County, in Henan Province in North China. The site denotes the earliest development

J

of the Peiligang culture in China, which is considered to be one of the worldwide centers of agricultural origins. The site was dated with conventional ^{14}C to between 9,000 and 7,800 cal BP (Henansheng 1999; Zhang et al. 1999).

Definition

Jiahu lies east of Mount Funiu in Henan Province. The Ni River currently runs south of the site; however, in ancient times, the Sha River ran to the north of the site (Li et al. 2003: 32). The site was initially excavated in 1962 and was excavated six times between 1983 and 1987 (Zhang et al. 1999). The most recent excavations were in 2001 (Zhang and Pan 2002). The site is 5.5 ha in size and includes several multiroomed houses (Henansheng 1999; see Liu 2004: 75 for an English summary). Three phases were identified at the site, phase one 7,000–6,600 cal BCE; phase two 6,600–6,200 cal BCE; and phase three 6,200–5,700 cal BCE (Henansheng 1999: 515). These dates were confirmed by TL and IRSL dating (Yang et al. 2005). These phases correspond to the early, early/middle, and middle Peiligang culture, respectively.

Key Issues/Current Debates/Future Directions/Examples

The significance of the Jiahu site is derived in part from the evidence of symbols or possible early writing (Li et al. 2003) and the early development of music including a crane-bone flute (Zhang et al. 1999, 2004). Stone tools and pottery appear to have been locally produced (Liu 2004: 78). Residues from pot sherds at the Jiahu site were found to contain an early type of alcohol made from rice and honey as well as other ingredients (McGovern et al. 2004).

Jiahu also has evidence for early pig domestication by 8,600 cal BP (Cucchi et al. 2011). Pig husbandry is thought to have occurred c. 8,000 BP in the Yellow River region, with suggestions of early domestication at Zengpiyan in Guangxi Province now discarded (Yuan 2006; Yuan and Flad 2002). New models of pig domestication support multiple independent centers of domestication (Cucchi et al. 2011: 11). Aside from Jiahu, early pig domestication sites such as Kuahuqiao, in Zhejiang Province, exhibit tooth crowding and tooth size reduction (Zhejiangsheng 2004: 252–269), and Xinglongwa in Jilin Province displays human-pig interactions in the form of pig burials in human graves (Yuan 2006). Based on second molar phenotypic traits, Cucchi et al. (2011) suggest that pigs at Jiahu display a shift towards domestication around 6,600 BCE. This concurs with stable isotope data from human bones; a shift towards increased animal protein consumption is evident from the first to second phase of occupation at Jiahu (Hu et al. 2006). The main plant components of the diet at Jiahu were C3 plants such as rice (Hu et al. 2006: 1328).

One of the most hotly debated issues stemming from the Jiahu site is the question of early rice cultivation (Liu et al. 2007). In the past debate has focused on whether this rice is domesticated or morphologically wild (Chen and Jiang 1997; Zhang and Wang 1998; Jiang and Liu 2006; Fuller et al. 2007; Liu et al. 2007). Claims for rice being in an early stage of domestication (Chen and Jiang 1997; Jiang and Liu 2006; Liu et al. 2007) are debated by Fuller et al. (2007), with debate related to the definition of early or later stage domestication. The rice at Jiahu is outside the modern geographical range for wild rice (Chen and Jiang 1997) although it is unclear whether it was outside the range for early Neolithic wild rice as well. This is especially difficult to determine given the climatic and environmental changes across the region over the past 9,000 years. Most recently, Zhijun Zhao, the paleoethnobotanist who examined the grains, has suggested the rice exhibited a large range of sizes indicating it was probably in the early stages of domestication (Zhao and Zhang 2009: 88, 93). The presence of large numbers of rice grains at the site at least indicates cultivation, if not domestication. Zhao and Zhang (2009: 93) also suggested that the numerous grains of soybean (*Glycine soja*) at the site were cultivated although they were morphologically wild.

The subsistence spectrum from Jiahu is similar to sites such as Hemudu and Kuahuqiao from

Zhejiang Province in South China, where rice was cultivated and a range of tubers and water plants were present in the waterlogged deposits (Liu et al. 2007). Other plant remains at Jiahu included acorns (*Quercus* sp.), water caltrop (*Trapa* sp.), lotus root (*Nelumbo nucifera*), walnut (*Juglans* sp.), and wild grapes (*Vitis* sp.) (Zhao and Zhang 2009).

Jijón y Caamaño, Jacinto

Florencio Delgado Espinoza
Colegio de Ciencias Sociales y Humanidades, Universidad San Francisco de Quito, Quito, Pichincha, Ecuador

Basic Biographical Information

Jacinto Jijon Y Caamaño was born on December 11, 1890, in Quito, Ecuador. He was the only child of Don Carlos Jijón, an important hacendado and

businessman, who died in 1908, when Jacinto was turning 18. He died on August 17, 1950, at the age of 60, and bequeathed part of his impressive library and museum to the Pontificía Universidad Católica del Ecuador, which is open to students and researchers. His house at the Circaciana in Quito now houses the Instituto Nacional del Patrimonio Cultural (National Institute of Cultural Heritage).

Major Accomplishments

During his childhood years, besides going to a private school in Quito, he was trained by the Salesian father and educator Jacinto Pankeri. After his father's death, he turned to father Federico González Suárez, archbishop of Quito, for mentorship. The archbishop had just published a monograph *Aborígenes de Imbabura y Carchi* (González Suárez 1910) and formed the Sociedad de Estudios Históricos Ecuatorianos y Americanos (SEEHA), with Jacinto as its youngest member. Inspired by his mentor's work, he began excavating on his own property, Hacienda Urcuqui and Hacienda Hospital, as well as on that of one of his friends, El Molino in El Quinche, along with father Pankeri who served as his field director and Juan León Mera as photographer and illustrator. Before leaving for La Paz as adjunct to the Ecuadorian Embassy in 1910, he excavated the Hacienda Ignaro. Upon his return from Bolivia in 1911, he resumed excavations at Urcuqui and extended his research to other areas of Imbabura.

At the age of 22, in the company of his friend Carlos Manuel Larrea and his mother, he moved to Europe. His first stop was the Congress of Americanist in London, and 3 months later they relocated to Paris, where under the auspices of Gonzalez Suárez, he interacted with Paul Rivet, who had served in Ecuador as physician for the French Geodesic Mission from 1901 to 1906. Rivet, then in charge of the Academy of Sciences of Paris, took Jacinto and Carlos Manuel under his wing, training them in physical anthropology and craniology and introducing them to French scientists. In 1914, they went to Spain and participated in a Geography congress in Sevilla, and in 1915 in Madrid, he published *Contribuciones al Conocimiento de los Aborígenes de la Provincia de Imbabura de la República del Ecuador* (Jijón y Caamaño 1912) and *El Tesoro del Itchimbía.*

In 1916, after his mother's funeral in Paris, he returned to Quito. His mentor, father Federíco González Suárez, died in 1917, and Jacinto succeeded the archbishop as president of the SEEHA. A year later, in 1918, the first *Boletín de la Sociedad de Estudios Históricos Americanos* appeared as a specialized journal in which Jijón himself published large parts of his works. That year, he published *Un cementerio Incásico en Quito y notas acerca de los Incas en el Ecuador* with Carlos Manuel Larrea (Jijón y Caamaño and Larrea 1918). A year later, he published *La Religion del Imperio de los Incas*, a then trendy topic inspired by the culture concept posited by Taylor (Vargas 1971) (Fig. 1).

Between 1918 and 1919, after writing a short essay on the artifacts from the coast (Jijón y Caamaño 1919), he devoted his interests to Chimborazo and Tungurahua provinces. In Riobamba, he excavated Macají, and San Sebastián de Guano, and the cemetery of Santa Elena near Ambato, and published *Puruhá*, *Contribución al*

Jijón y Caamaño, Jacinto, Fig. 1 Jacinto Jijón y Caamaño second form the left (National Library)

Conocimiento de los Aborígenes de la Provincia del Chimborazo (Jijón y Caamaño 1927). Here, he devoted his efforts to constructing a regional chronology, using Panzaleo culture as the main chronological marker. In Guano, he identified a widely dispersed assemblage, Tuncahuán, which included Carchi, Chimborazo, Cañar, Azuay, and even Manabí and Esmeraldas provinces. At this point he had already excavated in Manta and Cerro Jaboncillo, both in Manabí, returning in 1923 to define the Manteño culture associated with stone industry. His regional focus brought him into contract with Max Uhle, a renowned archaeologist who had excavated in Argentina, Perú, and Bolivia under the auspices of both the Museo Etnológico de Berlin and the University of Pennsylvania (Marcos 1988). Uhle's first task was to study the provinces of Cañar, Azuay, el Oro, and Loja, completing his task in the next 5 years, after which they went their separate ways. In 1920, SEEHA was recognized by Congress and transformed into the current Academia Nacional de Historia and its journal *Boletín de la Academia Nacional* (Jijón y Caamaño 1922). Jijón continued publishing his work in the bulletin and in 1923 began a publication series *Colección de Libros Raros*.

As a member of a rich family of hacendados, a leader in the textile industry, a fervent catholic, and president of the conservative party, he held strong conservative viewpoints until his death. He devoted time to publish two volumes of *Política Conservadora* in 1912 and 1934 (Jijón y Caamaño 1929; Jijón y Caamaño and Chávez 1981). His political activism was evident in his presidency of the Concejo de Quito in 1934 where he pushed for a conservative policy and the search for the Spanish heritage of Quiteños. He also contributed effort to publish the early cabildo papers found in the Quito Archive. In 1924, he bought arms in Colombia to lead a coup against President Gonzalo Cordova; however, his combative days ended after defeat in his first battle against the Ecuadorian army. He subsequently left Ecuador and established residency in Lima, where he met Uhle, Kroeber, and Tello and excavated Maranga, which was published in 1949 (Jijón y Caamaño 1949). He also published *Notas de Arqueología Cuzqueña* and began writing his monograph *Una Grán Maréa Cultural en el N-O de Sud América* (Salazar 1997).

Jijón y Caamaño, Jacinto, Fig. 2 Jacinto Jijón y Caamaño in his later years (National Library)

In 1933 he taught Ecuadorian Ethnography at the Universidad Central in Quito. During his stint as major of the City of Quito mayor of he produced in 1936, 1938 and 1949, three volumes on its Spanish history, and the first biography of the city's founder, Sebastian de Benalcazar (Jijón y Caamaño 1936, 1938) (Fig. 2).

During the 1940s, Jijón sought to synthetize the prehistory of Ecuador. In 1941 and 1943, four volumes entitled *El Ecuador Interandino y Occidental Antes de la Conquista Castellana* offered a comprehensive cultural history of Ecuador and introduced the study of philology and linguistics (Jijón y Caamaño 1943, 1945). In 1945 he wrote one of his masterpieces, *Antropología Prehispánica del Ecuador*, which was published post mortem by his wife and son in 1956 (Jijon y Caamaño 1997). One publication he never finished was *Las Culturas Andinas de Colombia*, which was also published posthumously in 1956. Also, in 1949 as one of the leading organizers of a colonial art exposition, he offered "Arte Quiteño, Breves Consideraciones Históricas."

Johnson, Matthew (Historical Archaeology)

Alasdair Brooks
The Grand Egyptian Museum (GEM) Project, Hill International, Giza, Egypt

Basic Biographical Information

Matthew Johnson, one of the leading theoreticians working in the archaeology of the late medieval and modern worlds, was born in Austin, Texas, in 1962 and has held joint US–UK citizenship since his birth. One of his formative archaeological experiences was the period which Johnson spent between September 1981 and June 1982 with the Norwich Survey, when he was involved with the post-excavation analysis and archive preparation of pottery and small finds from the late Anglo-Saxon to postmedieval periods from urban sites in Norwich, England. He would also spend an influential season working in Annapolis, Maryland, in 1985 as part of Mark Leone's Annapolis research program. Johnson's undergraduate and graduate degrees were all awarded by St. John's College, Cambridge University, between 1985 (BA) and 1990 (Ph.D.); his doctoral dissertation was on the subject *A Contextual Study of Traditional Houses in Western Suffolk, AD 1400–1700*.

Following his Ph.D., Johnson became Lecturer in Archaeology and Prehistory at the University of Sheffield (1988–1989) and was then appointed as a University of Wales Research Fellow in the Department of Archaeology at what was then still St Davids University College, Lampeter (1990–1991). In 1991, he was appointed Lecturer in Archaeology at the University of Durham, where he would remain until 2004, rising to the position of Professor of Archaeology before his departure. He was appointed Professor of Archaeology at the University of Southampton in 2004, becoming Head of Archaeology between 2005 and 2008; he was Deputy Head of School of Humanities (Research), between 2009 and the end of 2011. In January 2012, he took up a new

professorial post at Northwestern University in Evanston, Illinois. He has also held Visiting Fellowships at the University of California at Berkeley (1995); the South African Centre for Science Development (1997); the Centre for Medieval and Renaissance Studies, University of California at Los Angeles (1998); the Centre for Cultural and Environmental History, University of Massachusetts at Boston (1998); the University of Cambridge (2001–2002); Flinders University, Adelaide, Australia (2003–2004); Ruprecht-Karls-Universität, Heidelberg, Germany (2005); and the University of Pennsylvania (2008). He was elected a Fellow of the Society of Antiquaries of London in 2002 and was selected as a Guggenheim Fellow in 2019.

Major Accomplishments

Matthew Johnson is a one of the few historical (or postmedieval) archaeologists whose approaches to archaeological theory, particularly as regards the archaeology of capitalism, are widely known – and have been influential – outside of the subdiscipline of historical archaeology. Notwithstanding his dual British-American citizenship, and his current post in the United States, he is arguably the most important and influential theoretician working in the British postmedieval tradition. His books *The Archaeology of Capitalism* (Johnson 1996) and *Archaeological Theory: An Introduction* (Johnson 2019) form the centerpiece of his international reputation; the latter is on its third edition and has been translated into, among other languages, Spanish, Chinese, Serbian, and Korean. *The Archaeology of Capitalism* is a particularly important book for its study of the transition from feudalism to capitalism in Britain. While in some cases this builds on work by influential American historical archaeologists such as Mark Leone (e.g., 1995) and James Deetz (e.g., 1996), Johnson does so via a British-centered but internationally aware archaeological approach that roots the development of capitalism in the transformation of the British countryside in the late medieval period. This has helped to broaden both the geographical and disciplinary reach of archaeologies of capitalism internationally.

Alongside his theoretical work, Johnson has also made important and influential contributions to archaeological studies of British architecture and landscape of the period c. 1300–1800. Important works here include *Housing Culture: Traditional Architecture in an English Landscape* (Johnson 1993), *Behind the Castle Gate: From Medieval to Renaissance* (Johnson 2002 – nominated for the biennial Archaeological Book Prize), and *Ideas of Landscape* (Johnson 2006 – selected by Margaret Drabble as one of her books of the year). Among this work's influential strands has been what Johnson himself has – with full knowledge of the phrase's broader archaeological implications – termed a "loss of innocence" (Johnson 1997) in archaeological studies of British vernacular architecture through the consideration and integration of such topics as historical change, regional variation, and the application of theoretical approaches to buildings archaeology.

Johnson's most recent research projects build on both these theoretical and architectural/landscape strands. Castles have long been a particular focus of research, and from 2010 to 2014, he led an Anglo-American project studying Bodiam Castle in the south of England. This late medieval castle is one of the most iconic in England thanks to its evocative moated landscape. Johnson's research examined Bodiam not just in local, regional, global, and postcolonial contexts but also as a castle and landscape that formed part of a lived experience that encompasses such themes as social identity and political economy (Johnson 2017). In the field of theory, Johnson has recently turned his attention to the vernacular experience of archaeological theory or how archaeologists think while practicing archaeology at an everyday level. In order to provide this work a geographic focus, Johnson has been examining the practice of archaeology within the Wessex region of Southern England, which encompasses such iconic sites as Stonehenge, Maiden Castle, and Salisbury.

Johnson's trans-Atlantic background means that the archaeological community can continue

to look forward to thought-provoking work on the archaeology of the Atlantic world, both in terms of trans-Atlantic archaeological theory and the actual archaeology of trans-Atlantic colonial settlement (e.g., Johnson 2015). His current work traces material landscapes and identities from the English Middle Ages through to North American and Caribbean plantations and colonies, via feudal settlements in Scotland, Wales, and Ireland. His aim is to explore the landscapes, and material culture that people made and used, and how these interacted with the changing identities of the English and their neighbors over time; a book on this research is forthcoming.

Johnson, Matthew (Theory)

Robert W. Preucel
Department of Anthropology, Brown University, Providence, RI, USA

Basic Biographical Information

Known for his contributions to archaeological theory, medieval archaeology, and the archaeology of landscape, Matthew Johnson is one of the leading historical archaeologists of his generation (Fig. 1). Born in 1962 in Texas, he grew up in Norwich, England, and enjoys a dual US and British citizenship. Johnson received his B.A. in 1985, his M.A. in 1989, and his Ph.D. in 1990 from St. John's College, Cambridge University, under the direction of Ian Hodder. Johnson served as a Lecturer in Archaeology and Prehistory at the University of Sheffield from 1988 to 1989. Johnson was a University of Wales Research Fellow in

Johnson, Matthew (Theory), Fig. 1 Matthew Johnson. (Courtesy of Matthew Johnson)

the Department of Archaeology at St. David's University College, Lampeter, from 1990 to 1991. Johnson was a Lecturer and then Professor in Archaeology at the University of Durham from 1991 to 1998. Johnson became Professor of Archaeology at the University of Southampton in 2004 and Head of Archaeology from 2005 to 2008 and was then Associate Dean of the Faculty of Humanities from 2009 to 2011. Johnson is currently Professor of Anthropology at Northwestern University.

Johnson completed his graduate studies at Cambridge just at the time that postprocessual archaeology came of age. Johnson was both an enthusiastic advocate of this new movement and a sharp critic. This is well demonstrated in his engagement with the popular concept of agency. Johnson observed that while postprocessual archaeology placed great emphasis on the role of the individual as an active social agent, there was little focus on the individual in practice (Johnson 1989). For example, in his review of Mark Leone's (1984) famous study of William Paca's garden, he pointed out that Leone failed to consider how the interpretations of those who visited the garden varied across class, gender, and ethnicity lines. Johnson also noted that the discussions of agency often neglected a consideration of structure, which was problematic since agency exists in a dialectical relationship with structure. Different sorts of social structures produce and are produced by different sorts of agency (Johnson 2000: 213). This insight caused him to propose the idea of a "historicity of agency," whereby models of agency are constructed appropriate to different epochs or periods.

Major Accomplishments

Johnson's early work used domestic houses and castles as a means of understanding the transition between feudalism and capitalism from the later Middle Ages to the beginnings of the Industrial Revolution. One of the most distinctive indexes of this transition is the "process of enclosure," the appropriation of common rights to an individual usually represented physically by hedges, fences, and walls demarking fields (Johnson 1991: 160). The process of enclosure, however, led to both intended and unintended consequences. It facilitated innovation and the rise of farming for profit. But it also let to the breakdown of community ties and the rise of class relations. In *Housing Culture* (Johnson 1993), he adopted the structuralist approach of Henry Glassie and James Deetz to argue that the structure and organization of domestic architecture relates not only to economic considerations but also to ideological ones as well. Indeed, he suggests that it is impossible to separate them out.

Johnson builds upon this research to contribute to an archaeology of capitalism, a field of growing interest in historical archaeology. Capitalism refers to a set of social relations linking landowners and patrons with workers and laborers. These social relations are classically unequal in the sense that laborers do not control the fruit of their labor, rather this is controlled by the landowners. Johnson (1996: 3) regards enclosure and commodification as emergent structures that unfolded in the late medieval period and achieved their full realization in industrial capitalism. They are not limited to a single domain, rather they cut across a range of spheres such as religious, agrarian, public, and domestic and are part of the genealogy of a disciplinary society.

More recently, Johnson has developed a sophisticated critique of landscape archaeology. In his book *Ideas of Landscape* (Johnson 2006), he observes that landscape archaeology especially as it is practiced in Britain is undertheorized. It is largely based on the work W. G. Hoskins (1955) and grounded in the ideas of English Romanticism. The Romantic tradition gives rise to an empirical approach based in field walking. Johnson argues that meaning does not just emerge from the landscape by itself. It is created and shaped as much by ourselves in the present, through our own habitual practices and ways of seeing, as it is by the activities of people in the past. His key insight is that we need to question the assumption that there is only one way of looking at and responding to landscape.

Johnson is well known for his general syntheses of archaeological theory. His book

Archaeological Theory: An Introduction (Johnson 1999) set out to demystify theory. As the screenwriter Richard Curtis might say, theory, actually, is all around. It underpins everything we do – from where we go to dig to what we choose to record – and to how we interpret what we find. Johnson writes with an engaging self-reflexive style to draw students into the complex debates about epistemological dilemmas, ethical stances, and political realities. Before they know it, they have become fluent in the language of archaeology and, equally importantly, are able to generalize this specialized form of knowing to other related domains.

Jokilehto, Jukka

Henry Cleere
Institute of Archaeology, University College London, London, UK

Basic Biographical Information

Jukka Jokilehto was born in 1938 in Helsinki, where he graduated from the Polytechnic in architecture and town planning in 1966. After a decade working in architectural practices in Finland, he took part in a number of courses on the conservation and restoration of historic structures around Europe, notably those on the restoration of monuments and sites at ICCROM (International Council for the Study of the Preservation and Restoration of Cultural Property) in Rome and on the conservation of historic structures at IoAAS (the Institute of Advanced Architectural Studies) at the University of York, where he was awarded the degree of Doctor of Philosophy (D.Phil.) in 1986.

Major Accomplishments

In 1972, Jukka Jokilehto joined the staff of ICCROM, becoming responsible in the following year for its program in architectural and urban conservation. Over the next two decades, he trained many hundreds of architects, planners, and conservators from every continent, with all of whom he has maintained close contact. Visits to

sites and monuments formed an essential component of these ICCROM courses, and as a result, Jukka became familiar with the concepts and practices for conservation and restoration across the whole gamut of human cultures. He remained with ICCROM until his retirement in 1998 after 6 years as Assistant Director-General. During his long years of service, he represented ICCROM at many meetings around the world, notably those of the UNESCO World Heritage Committee and those leading up to the 1999 Second Protocol of the 1954 UNESCO Convention for the Protection of Cultural Property in the Event of Armed Conflict (the Hague Convention). He is currently Special Advisor to the Director-General of ICCROM.

After his retirement from ICCROM, he also worked closely with ICOMOS (International Council on Monuments and Sites) as an advisor on World Heritage (2000–2006), as President of the International Training Committee, and as a member of the International Committee on the Theory and Philosophy of Conservation and Restoration. He is currently Professor at the University of Nova Gorica (Slovenia), jointly with the UniversitàIuav di Venezia. His wide consultancy portfolio is mainly directed toward the preparation of nominations to the UNESCO World Heritage List, management and urban conservation plans, and lecturing on the history and theory of conservation and on the management of the built heritage at universities around the world.

The last sentence of the Preface to the *Festschrift* published by ICCROM in 2008 admirably summarizes the esteem accorded to Jukka Jokilehto by colleagues and students alike over his long career: "May these essays give as much pleasure and inspiration to Jukka as he has given to so many others."

Jones, Rhys Maengwyn

Kellie Pollard
College of Indigenous Futures, Arts and Society, Charles Darwin University, Darwin, Australia
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Rhys Maengwyn Jones (1941–2001) (Fig. 1) was born in Wales on 26th February 1941. He died in Canberra, Australia, on 19th September; 2001. Jones received his primary and secondary education in Wales, where he grew up. He received a Master of Arts from Cambridge University, England, in 1966. After that he moved to Australia. In 1972 he was awarded a Ph.D. in archaeology from the University of Sydney. In 1969 Rhys Jones joined the Australian National University as a Research Fellow with the Research School of Pacific Studies. In 1993, he was awarded a personal Chair.

Rhys Jones was a prolific academic writer who published more than 200 articles and books. His research on Australia established him as a scholar

Jones, Rhys Maengwyn, Fig. 1 Rhys Jones. (Courtesy Betty Meehan)

of international standing. Universities in Europe, South East Asia, South America, Canada, North America, and the Pacific hosted his lectures on human evolution and archaeology. In 1995–1996, he held the prestigious Chair of Australian Studies, Harvard University, and in 2001 he became an Honorary Professor at the Scarab Research Centre at the University of Wales, Newport.

Along with colleagues such as Jack Golson, Betty Meehan, and Peter White, he played a key role in the professionalization of Australian archaeology in the 1960s and 1970s and in the establishment of the Australian Archaeological Association. He served on Faculty Boards and on advisory, research committees, and councils at the Australian National University and was an elected member of the Council of the Australian Institute of Aboriginal and Torres Strait Islander Studies. He was Vice-President of the Australian Academy of the Humanities from 1984 to 1987. His professional service to archaeology includes being a co-editor of *Mankind*, the Journal of the Anthropological Societies of Australia, from 1965 to 1972, and being President of the Australian Archaeological Society from 1977 to 1979. His contributions to Australian archaeology were recognized by the Australian government in 2003, when he was posthumously appointed an Officer of the Order of Australia, "for service to archaeology, particularly in the areas of research and teaching, and as a leader in matters relating to world heritage, conservation and indigenous social justice issues" (Smith 2003: 51).

Major Accomplishments

Rhys Jones was an outstanding archaeologist whose seminal works shaped critical research directions at a time when Australian archaeology was in its infancy. He was a member of a generation of intellectuals with European pedigrees who moved to Australia and established archaeology in this country in the late 1960s and early 1970s. Jones' research focus was on the antiquity of human occupation of the continent and the complex archaeological signature of human-environment relationships across the Pleistocene-Holocene transition. His influence extended far beyond his own research projects. He supervised successive generations of Australian students as they attempted to answer the most pressing questions of the times – the first colonization of the Australian continent, human evolution and land use, and the complexity of Indigenous settlements.

Rhys Jones' scholarly publications attest to his eclectic interests within archaeology. His interest in sociocultural evolution is evident in his doctoral study of the origins and evolution of Tasmanian Aboriginal people. This thesis is still considered a landmark study for its thoroughness, intellectual scope, and complexity of approach to archaeological theory and method.

Over a career spanning 40 years, Rhys Jones produced scholarship on the antiquity and

significance of some of the most important finds in Australian archaeology. His involvement in the recording, salvage, and research of the oldest recorded human burials in Australia at Lake Mungo led to seminal publications on the significance of these remains to theories of human evolution (Bowler et al. 1969). Although a trained scientist Jones understood and respected the local Indigenous community's reaction to the research into human remains at Lake Mungo, and in 1991 he was involved in the repatriation of these remains for reburial.

An important focus of Jones' research was the antiquity, land use, and settlement patterns of Aboriginal people in the Arnhem Land and Kakadu regions in northern Australia. In 1981 he directed a major interdisciplinary archaeological expedition to Kakadu National Park. Along with his life partner, Betty Meehan, he worked in remote Aboriginal communities in the Northern Territory in the 1980s. As a result of his experiences there, Jones was active in establishing a new frontier of knowledge in an Australian context: ethnographic approaches in Australian archaeology. Jones and Meehan's work inspired a spate of ethnographic studies among archaeologists in diverse geographic and environmental contexts in Australia.

Along with colleagues such as Jack Golson, Jim Allen, and John Mulvaney, Rhys Jones initiated research into the interrelationships between environment, ecology, and Indigenous peoples in the Australasian region. Jones' seminal paper, "Firestick Farming" (Jones 1969), broke down the perception of Aboriginal people as "unchanging people in an unchanging landscape" and is still cited extensively, while his paper "Why Did the Tasmanians Stop Eating Fish?" (1978) became a central resource in debate on the impact of cultural conservatism in Indigenous societies. In addition, Jones was a leader in advocating a scientific approach to Australian archaeology, expressly through the use of new scientific methods in dating rock art and investigation of the potential of paleoclimatic for the analysis of occupation deposits.

Rhys Jones' fieldwork with Aboriginal people in remote parts of northern Australia taught him much about Indigenous people's relationships to land. His standing with the Aboriginal people with whom he worked can be gauged by the Aboriginal Honours that were bestowed on him. He was invited to attend Kunapipi ceremonies in Arnhem Land in 1972 (twice) and 1986. Moreover, he was co-recipient of Rom ceremonial regalia in 1982. He was given the kinship designation (skin name) Wamut with the Galamagondidja Baparru clan of the Gidjingarli people, Arnhem Land, Northern Territory, Australia.

Rhys Jones accomplishments in Australian archaeology spanned all current and developing theories and methods in archaeological scholarship and related fields. He published independently and with colleagues on archaeological research in Europe, the Middle East, South East Asia, Oceania, and his native country of Wales. He was a prolific academic writer, publishing more than 200 articles and books, and spoke fluent Welsh and French. Over a forty-year period he attended, organized, and delivered seminars, debate sessions, public and university lectures, workshops, symposia, and conferences for which he produced more than 60 publications about human evolution and the colonization of the Australian continent.

Rhys Jones was a public intellectual whose views helped to shape the Australian public's appreciation of their past. He had a deep knowledge of Australia's Indigenous heritage and a rare ability to engender enthusiasm for this subject in both students and members of the general public. His career spanned 30 years in film, television, and radio documentaries, some of which he co-produced and appeared in, and in newspaper articles. Jones made major contributions to the quality of Australian society through enhancing a broad community understanding of Indigenous cultures. He gave frequent presentation on the cultural history of Tasmania and once gave a lecture aboard the *Icebird*, an ice-breaking ship travelling to Antarctica to resupply scientific personnel.

Much of Jones' research and public outreach was conducted in Tasmania. Jones' research on human evolution and occupation antiquity in Tasmania revolutionized popular perceptions of the sophistication and complexity of Tasmanian Aboriginal social organization and culture. The film that he co-wrote and appeared in, *The Last Tasmanian*, won first prize at the Adelaide Film Festival, the 1978 Logie for the best Australian documentary, and a silver medal at the Commonwealth Film Festival 1978, Cyprus. However, the film proved to be controversial as it was interpreted in the popular media as denying the existence and survival of Tasmanian Aboriginal people.

One of Rhys Jones' most significant accomplishments in this area was the World Heritage Listing of archaeological sites on the Franklin River (Kiernan et al. 1983). Jones' scientific research was fundamental to the nomination and subsequent listing of this area and his public engagement essential to lifting the public profile of the region. In 1981 he directed the discovery and archaeological excavations of the Kutikina Cave (formerly Fraser Cave), Franklin River, southwest Tasmania. His analysis of archaeological finds at Kutikina Cave in Tasmania established the antiquity of human occupation in Tasmania, contributing to the nomination of the nearby Franklin River to the World Heritage List. Working with colleague John Mulvaney, Rhys Jones played a critical role in the preservation of archaeological sites under threat by the damming of the Franklin River. Along with international colleagues Jones and Mulvaney took out a full-page newspaper advertisement affirming the significance of Kutikina Cave and the Franklin area as part of the world's cultural heritage.

Rhys Jones had an extraordinary intellect and capacity to reach out to diverse peoples. He was a natural linguist and could converse in Gu-jingarliya with the Anbarra people of Arnhem Land and in Tok Pisin with the people of Papua New Guinea. He was literate in Italian, Spanish, German, and Renaissance Latin. His scholarship established new directions in Australian archaeology.

Rhys Jones' outstanding contribution to Australian archaeology was honoured in the volume *Histories of Old Ages*: *Essays in Honour of Rhys Jones* (Anderson et al. 2001). The Australian Archaeological Association recognizes his enduring contribution each year in its award of the Rhys Jones Medal for academic excellence in Australian archaeology.

Jorge, Vítor Oliveira

Vítor Oliveira Jorge
Archaeology and Heritage Studies, Faculty of Arts, University of Porto, Porto, Portugal

Basic Biographical Information

Vítor Oliveira Jorge (Fig. 1) is a Portuguese archaeologist. Born in Lisbon in January 1948, he was awarded a degree in history (with a dissertation on Paleolithic archaeology) from the Faculty of Arts of the University of Lisbon in 1972. After being a lecturer at the University of Luanda (Angola), a territory where he had carried out several field research projects, he moved to the University of Porto, in the north of Portugal, where he taught from 1974 to 2011. His Ph.D. dissertation was awarded in 1982 on the basis of his analysis of passage graves (megalithic monuments) in the north of Portugal, in the fourth and fifth millennia BCE. The same theme was the object of his "aggregation" (public examination as a professor) in 1989. Vítor Jorge became a full professor of his faculty and university in 1990. He has been a member of the Department of Cultural Heritage Sciences and Techniques of the Faculty of Arts of the University of Porto since its creation in 2007. He was also a member of the research group of Centro de Estudos Arqueológicos das Universidades de Coimbra e Porto (CEAUCP/CAM) – an archaeological research unit that included archaeologists and heritage specialists from the universities of Porto and Coimbra and from the Mertola's Archaeological Camp – since its foundation and until 2014. Now (since January 2015) he is a researcher of the Instituto de História Contemporânea of the Universidade Nova de Lisboa.

In addition to being an archaeologist, Vitor Jorge is a poet, who has published around 20 books, and an essayist.

Jorge, Vítor Oliveira, Fig. 1 Vítor O. Jorge

Major Accomplishments

The archaeological career of Vítor Oliveira Jorge, who has kept active after his retirement in 2011 (both as a field archaeologist and as a researcher), has covered a range of themes. Until 1972, one of his interests was the Paleolithic archaeology of southern Portugal, namely, the Early and Middle Paleolithic, with a particular concern with the pebble tool industries. In 1973 and 1974, he conducted research on the archaeology of the southwest of Angola prior to Portuguese colonization, especially in the Huíla Plateau and in central Angola. From 1975 to 1994, he studied the Neolithic (megalithic) mounds of northern Portugal (namely, in the area from the border with Galicia to the river Douro to the south), with an emphasis on spatial and social archaeology, trying to focus on necropolis and their settings, rather than on isolated monuments, and showing the polymorphous character of these monuments.

From 1989 until the present, he has focused on Copper Age and Bronze Age hill sites (third to second millennia BCE) in the high Portuguese Douro basin (Vila Nova de Foz Côa region), as a continuation of his interest in prehistoric architectures and their relationships with the territories

where people settled. He is one of the directors of the excavation of the hill site of Castanheiro do Vento (1998–2018), an important Chalcolithic hill precinct located in the territory of the Foz Côa municipality. This research has changed the way archaeologists currently look at these kinds of sites, wrongly named "fortified settlements." Vítor Jorge contends that they probably were not the common places where people lived but ceremonial and symbolic devices connected with the constitution of local community identities and the emergence of elites.

In 1994 and 1995, when he was Dean of the Faculty of Arts of the University of Porto, Vítor Jorge took a public position in favor of the conservation of the rock art complex of the Côa valley in the northeast of Portugal (not far from the area he studied as a field archaeologist). In 1995 and 1996, he was the head of the Commission that prepared the installation of the Côa Valley Archaeological Park, and in 2001 the President of the Portuguese Republic granted him the Merit Insignia for his actions to protect Portuguese cultural heritage. After his retirement, in 2012, the Faculty of Arts of the University of Porto, where he has taught for 37 years, conferred him its Golden Medal, in a public ceremony where a book in his honor was presented.

Professor Vítor Jorge has organized and published the proceedings of many scientific meetings, namely, the I (Porto 1993) and III (Vila Real, in collaboration with the local university, the University of Trás-os-Montes e Alto Douro) Congresses of Iberian Archaeology (the proceedings of these congresses were published by SPAE and ADECAP, 8 volumes and 10 volumes, respectively). He is the head of two nonprofit scientific associations, the Sociedade Portuguesa de Antropologia e Etnologia (SPAE) and the Associação para o Desenvolvimento da Cooperação em Arqueologia Peninsular (ADECAP). From 1998 to 2011, this latter association published a journal in English, the *Journal of Iberian Archaeology*.

Lately, Professor Jorge has developed an interest in philosophical issues connected to his research themes in archaeology and cultural anthropology, namely, the relationships between culture and nature, humans and animals, objectivity and subjectivity, history and temporality, space and place, gender, and Lacanian psychoanalysis. These issues have driven him to study and to give short courses on the work of critical authors such as Giorgio Agamben and Slavoj Zizek. Since his youth, Vítor Jorge has struggled for a more intimate connection between archaeology (especially the so-called prehistoric archaeology) and the problems raised by contemporary critical thought, a connection that he thinks is crucial for the development of archaeology itself as a mature discipline.

Jorvik Viking Centre

James Symonds
ACASA Archaeology, University of Amsterdam, Amsterdam, Netherlands
Department of Archaeology, University of York, King's Manor, York, UK

Basic Information

The Jorvik Viking Centre opened in York in 1984, following a 5-year excavation by the York Archaeological Trust. This "Viking Dig" (Hall 1984) had revealed that up to 9 m of archaeological deposits had built up in the Coppergate area of the city and that these moist organic-rich deposits contained the remains of wood, thatch, and many thousands of artifacts. The anaerobic nature of these deposits meant that textiles and leather were all well preserved. In total the dig recovered 250,000 pieces of pottery, 5 t of animal bone, and 40,000 other objects. The dig demonstrated that Jorvik had grown dramatically in the late ninth and tenth centuries, with new streets, a new arrangement of development plots, and new types of urban buildings. All of this was fuelled by craft production and trade. This discovery allowed the York Archaeological Trust to rewrite the history of town life in England, showing how this period was not an era of looting, or destruction, as many had thought, but one in which the foundations of medieval urban prosperity had been laid.

Major Impact

The Jorvik Viking Centre (http://www.jorvik-viking-centre.co.uk/) has welcomed over 17 million people through its doors since 1984 and today has about 400,000 visitors a year. The attraction contains a ride-based experience where visitors are carried around the replicated site of the Viking site on capsule cars that carry six people each. Visitors are able to see reproductions of the Viking houses where they stood over 1,000 years ago, see animatronics depicting the Viking inhabitants, and witness the sounds and smells of the time, including the world's famous Viking "man on the toilet." The ride is complemented by a series of gallery spaces which give visitors a variety of perspectives on Viking age life (Fig. 1).

Joukowsky, Martha Sharp

Susan E. Alcock
Joukowsky Institute for Archaeology and the Ancient World, Brown University, Providence, RI, USA

Basic Biographical Information

Martha Sharp Joukowsky is an archaeologist who has worked in numerous parts of the world, including Lebanon, Hong Kong, Turkey, Italy, Greece and, most extensively, Jordan. Her research encompasses studies of the domestication of plants and animals, the advent of Middle East urbanism and the varied cultural developments in Anatolia, Syro-Palestine, Iraq and Iran, from prehistory to the Roman periods. Her doctoral work (Ph.D. Paris I-Sorbonne 1982), published as *Prehistoric Aphrodisias* (1996b), engaged with the Neolithic through Bronze Age periods at the site of Aphrodisias in Turkey.

Joukowsky is a 1958 graduate of Pembroke College, the then coordinate women's college to Brown University. Until her retirement, she was Professor of Old World Archaeology and Art and of Anthropology at Brown, where she also serves as Trustee Emerita; she was recognized with the honorary degree of Doctor of Humane Letters by Brown in 1985. Joukowsky was elected President of the Archaeological Institute of America (AIA) in 1989, serving a 4-year term; the AIA's Distinguished Service Award bears her name and that of her husband, Artemis A.W. Joukowsky. The pair was presented with the AIA's Bandelier Award for Public Service to Archaeology in 2010.

In 2004, Brown University established the Joukowsky Institute for Archaeology and the Ancient World which is dedicated to promoting the investigation, understanding, and enjoyment of the archaeology and art of the ancient Mediterranean, Egypt, and Western Asia, through active fieldwork projects, graduate and undergraduate programs, and public outreach activities.

Major Accomplishments

Joukowsky directed a near 20-year long archaeological campaign at the Great Temple at Petra (southern Jordan), which has led to numerous detailed publications, student research projects and widely viewed documentaries and other public presentations. The excavation, sponsored by Brown University, revealed an impressive structure built, from the local "rose red" sandstone, on an artificial terrace along the city's main colonnaded street between the late first century BCE and the first century CE. The multi-level design of the 'temple' (its precise range of functions is sometimes debated) is especially noteworthy for its large porticoed courtyard, 120 columns (topped by elephant-headed capitals) and a small theatral area inserted into the structure's interior. The Brown University Great Temple team also explored a huge cistern, bath system and Residential Quarter. Almost completely buried at the project's inception, the complex today has been conserved and substantially restored, and is a major visual landmark in the Petra city center. Joukowsky also used the Great Temple as a laboratory for introducing a range of scientific techniques, many pioneering for their time in Jordan, including the use of

Ground Penetrating Radar (GPR) and 3D modeling and visualization studies. All Great Temple data are currently available through Open Context of the Alexandria Archive Institute.

Apart from her substantive publications deriving from fieldwork, Joukowsky is credited with writing one of the most influential handbooks in the field, *A Complete Manual of Field Archaeology: Tools and Techniques of Field Work for Archaeologists* (1980), which went through eight editions before going out of print. Among her several other books is *Breaking Ground: Pioneering Women Archaeologists* (2004), co-edited with Getzel Cohen, which examines the lives of several pioneer female archaeologists in the early days of the discipline. This project was also expanded into a web-based encyclopedia, *Breaking Ground: Women in Old World Archaeology*, co-edited with Barbara Lesko.

Journal of Archaeological Method and Theory

Catherine M. Cameron[1] and James M. Skibo[2]
[1]Department of Anthropology, University of Colorado, Boulder, CO, USA
[2]College of Arts and Sciences, Illinois State University, Normal, IL, USA

The *Journal of Archaeological Method and Theory* (*JAMT*) is a quarterly publication of Springer Science+Business Media publishers (Springer). *JAMT* presents method- or theory-focused papers covering issues that are at the cutting edge of the discipline. The leading journal in its field, *JAMT*, also includes topical syntheses that critically assess and integrate research on specific subjects in archaeological method or theory, as well as examinations of the history of archaeology. The journal actively recruits "theme" issues where groups of authors address a particular theme often using regional case studies to illustrate method- or theory-related topics. Authors of *JAMT* articles include scholars from around the world, and each submission undergoes a rigorous peer-review process that insures articles published in the journal are of the highest possible quality. Articles that are accepted for publication are aimed at an international audience of archaeologists, students of archaeology, and practitioners of closely related disciplines. The journal's editorial board includes distinguished archaeologists with worldwide knowledge of the past (the Americas, Asia and the Pacific, Europe, and Africa) and expertise in an extensive range of methodological and theoretical issues.

The founding editor of the journal, Michael Brian Schiffer, noted in the introductory statement in the first volume (Schiffer 1994: 2) that the "journal will be a home for substantial syntheses" as well as "contributions to the history of archaeology, method-or theory-focused case studies, and significant explorations on the frontiers of method and theory." The journal's

genesis can be traced back to 1978 with *Advances in Archaeological Method and Theory*, a yearly edited volume published by Academic Press. The goal of that publication, which continued with Academic Press for 11 volumes and later with the University of Arizona Press for 5 volumes, was the presentation of topical syntheses usually solicited by the editor. The series filled an important need as theoretical papers during that time often had difficulty finding a publishing outlet. By the early 1990s, Schiffer decided to shift from yearly publications to a quarterly journal, its present format. Schiffer continued as editor until volume 6 in 1999, and James Skibo and Catherine Cameron became coeditors in 2000. Since the beginning of their tenure, they have alternated between senior and junior coeditor. Their editorship coincided with the transformation in academic journal publishing from a reliance on individual and institutional subscriptions of hard copies of the journal to a dominance of electronic publication and downloads of individual articles. With the guidance of Teresa Krause, (Senior Editor, Social Sciences), of Springer, journal readership expanded dramatically, and currently there are tens of thousands of downloads each year from all over the globe. Although the journal has always been international in scope, the number of international authors and reviewers has also increased.

The major accomplishment of *JAMT* since its inception has been to serve as an outlet for the latest innovations in the field of archaeology. Tracking *JAMT* articles over the years illuminates how archaeology has developed theoretically, ranging from efforts to build on commonly used theoretical approaches to dramatically divergent approaches that take archaeology in startlingly new directions. *JAMT* has also been the first to publish important methodological advances. Since our articles are aimed at a worldwide audience, the new methods proposed by our authors are generally those that could be (and have been) applied to the archaeology throughout the world. Traffic on the online version of the journal shows that in addition to downloads of the most recently published articles, many older articles are also frequently downloaded indicating that *JAMT* has published a number of "classic" articles in the field that continue to be cited even years after publication. Another accomplishment of the journal has been to highlight the work of younger scholars who often are at the forefront of theoretical and methodological developments in archaeology. Both the journal's founding editor, Michael Schiffer, and its current editors have made efforts to help young scholars develop their ideas into valuable, publishable papers. Finally, the *Journal of Archaeological Method and Theory* has developed an active and experienced editorial board whose members serve as both springboard and sounding board for the latest ideas published in *JAMT*.

In 2009, the journal began to be covered by the ISI Social Science Citation Index, significantly heightening its profile. *JAMT*'s impact factors are consistently among the highest among all archaeology journals. As a result of the increased size and international scope of our authors, reviewers, and audience, the journal has experienced a significant expansion of the number of papers it receives each year. Importantly, we are part of Springer's *Online First* system which allows our papers to be published online as soon as they have been accepted and copyedited. They are later placed into one of our quarterly issues, but until then our subscribers have access to the most current research available. In order to stay in close touch with the most current developments in our field, we periodically enlist new, energetic board members to help us to recruit the latest high-profile studies. *JAMT* promises to be a leading journal in archaeological method and theory well into the twenty-first century.

Journal of Cultural Heritage Management and Sustainable Development

Luca Zan
Department of Management, University of Bologna, Bologna, Italy

Brief Definition of the Topic

JCHMSD was launched in 2011. Just the first issue has been published when these notes were under writing. In this case, more than investigating actual contents and distinguishing features as they appear from various volumes, the only thing to do is to look at the declared strategies by the editors.

The journal is calling firstly for papers on immovable cultural heritage, though also intangible heritage will be involved. In any case, a distinctive focus is the issue of sustainability, one of the more problematic elements in the field of heritage. The bridging between heritage discourse and sustainability is underlined as one of the distinguishing features of the journal.

Also, a variety of approaches are encouraged, from theory to practice. In any case, an emphasis on practices, on their improvement or the development of innovative practices can be pointed out (the call for paper refers to "positive contribution"). Needless to say, a strong interdisciplinary attitude is called for, and an international focus is at the base of the journal.

Each article is 2,000–5,000 words in length, which once again underlines the nature of the journal as addressed to an audience of practitioners, or in any case to experts and scholars that have substantive interests in the field, more than abstract theoretical concerns. In other words, it seems to look for kind of phenomenon-driven rather than theory-driven research.

Submitted articles are subject to double-blind review. The journal is published by Emerald.

Journal of Heritage Tourism

Dallen J. Timothy
School of Community Resources and Development, Arizona State University, Phoenix, AZ, USA

J

Introduction

Tourism based on living traditions, built heritage resources, and intangible culture is one of the most pervasive forms of tourism. It involves many different resources, and people's motivations for visiting are manifold (McKercher and du Cros 2014; Timothy 2011). Many places depend almost entirely upon the cultural past for their tourism-based economies, resulting in many political, social, ecological, and fiscal implications (Timothy 2011, 2016). This condition has resulted in considerable academic interest in heritage tourism since the late 1980s. While cultural/heritage tourism specialists have published for many years in a wide array of social science journals, the *Journal of Heritage Tourism* (JHT) was established in 2006 to provide an international, peer-reviewed outlet for the dissemination of scholarly research specific to this subfield. JHT publishes full-length research articles, shorter pieces/research notes, and book reviews of tomes relevant to all aspects of culture and heritage. As a transdisciplinary journal, it provides a venue for the consolidation of theoretical and

empirical knowledge about cultural heritage and visitor use from a multitude of perspectives.

Definition

JHT was originally published by Channel View Publications in Bristol, England. The journal was sold to Taylor and Francis in 2008 and is now published by Routledge six times per year. Increased interest in the journal has seen it grow from two issues in the first volume to five issues in 2017 and now six issues per annum beginning in 2018. Information about the journal and submissions guidelines can be found at http://www.tandf.co.uk/journals/rjht. The journal has a broad scope and encourages creative social science research on all visitor- and resource-related topics pertaining to the human past and cultural present. The journal is edited by Professor Dallen J. Timothy of Arizona State University. The editorial board is comprised of scholars from a range of disciplines, all of whom are well-recognized researchers or up-and-coming scholars in the field. Board members represent social scientists, ICOMOS team members, and UNESCO officers from all over the world, known for their expertise in heritage management, conservation, and tourism. The journal is indexed in CAB Abstracts; Cambridge Scientific Abstracts; Current Abstracts; EBSCOhost; Emerging Sources Citation Index; Global Health; Leisure, Recreation and Tourism Abstracts; Leisure Tourism Database; OCLC – Environmental Sciences and Pollution Management; Reuters Web of Science; Scopus; and World Agricultural and Rural Sociology Abstracts. It currently has an unpublished impact factor of 0.99 and is expected to have a published Thomson Reuters impact factor in the near future.

Key Issues/Current Debates/Future Directions/Examples

Some of the most prominent themes appearing in the journal include personal and national identity, diasporas and migration, cultural landscapes, religious pilgrimages and sacred site management, interpretation, visitor management, economic impacts, policies, UNESCO "branding," authenticity, and nostalgia. The journal also publishes special theme issues once or twice per year. Since its foundation in 2006, theme issues have focused on managing World Heritage Sites, identity and representation in ethnic tourism, natural heritage and biodiversity, Chinese heritage cities, heritage cuisines, sport heritage, cultural tourism in the Caribbean, historic hotels, and heritage trails. Future theme issues are planned around the topics of regional identity, indigenous tourism, and innovation and technology.

Journal of Human Evolution

Eric Delson[1,2] and David R. Begun[3]

[1]Department of Anthropology, Lehman College and the Graduate School, City University of New York, New York, NY, USA

[2]Department of Vertebrate Paleontology, American Museum of Natural History and New York Consortium in Evolutionary Primatology, New York, NY, USA

[3]Department of Anthropology, University of Toronto, Toronto, ON, Canada

Basic Information

The *Journal of Human Evolution*, known to all paleoanthropologists as JHE, is the leading

technical outlet for articles and news notes in human and nonhuman primate evolution, Paleolithic archaeology, and geochronological, taphonomic, and faunal studies related to those topics. It was founded in 1972 by Brunetto Chiarelli of the Anthropological Institute at the University of Florence, Italy. He produced 14 volumes through the end of 1985, with a wide view of "human evolution" including most of physical anthropology and some allied disciplines. A laxity of the reviewing process among other factors led Academic Press, which actually owned the journal (as does its successor Elsevier), to seek new editors.

Peter Andrews (London) and Eric Delson (New York) reorganized JHE, adding a new Board of Associate Editors with the express plan that they would coordinate review of all standard submissions (other than brief notes and book reviews), combining 3 external reviews with their own comments for final decision by an Editor. New manuscripts began to be received in December 1985, and after two issues of papers accepted by Chiarelli, the first issue under the new editorship appeared as volume 15, number 3, with a cover date of March 1986. Unfortunately, in part due to the unavailability of most manuscripts submitted to the previous editor, this issue actually was published near the end of 1986, and with no backlog of submitted papers to draw on, publication dates were delayed. This anachronistic situation persisted for several years, so that each article contained its month of publication (as well as dates of article submission and acceptance), through late 1988, when the September 1988 issue appeared that month. In the meantime, Chiarelli started a competing journal, *Human Evolution*, which never made much headway and appears to have ceased publication now.

JHE has continued to expand in popularity, eventually moving to 12 single-issue volumes per year, with 1647 pages in 2016. Numerous special issues have appeared, beginning with one in the December 1986 issue (published September 1987) drawn from contributions to a conference in honor of Desmond Clark (guest edited by J. W. K. Harris and John Yellen); others have covered such topics as primate systematics and evolution (from an early meeting of the Willi Hennig Society), primate locomotor evolution, several on behavioral ecology and/or paleontology of various primate groups, site-focused issues such as those on Atapuerca and the Turkish Miocene site of Paşalar, the *Homo floresiensis* material, "Paleoanthropology meets Primatology," Early-Middle Pleistocene paleoenvironments in the Levant, Excavations at Schóningen and most recently (September 2016) "Food materials testing and its relevance for primate biology."

The pattern of two Co-Editors has been retained since 1986, with a retiring Editor remaining "in harness" for a final year to complete production of articles (s)he has handled and then becoming Special Issues Editor. Following Andrews and Delson, 10 additional Editors have served an average of 6 years, with the two current (2017) Editors in their fourth and first year, respectively. Following the tradition set by Delson and Andrews, co-editors are often from the USA and elsewhere, generally the UK, but currently the editors are Spanish and USA, with the Special Issues Editor from the UK. The number of Associate Edtors (AEs) has risen from 26 to 41, in part due to the conscription of past Editors as permanent AEs; others are appointed for terms of 3 years and often reappointed once. There is a strong international flavor to the editorial board, with current AEs from the USA, UK, Australia, Belgium, Canada, France, Germany, and Spain. Gender diversity is also strong on the board, which, as in the field of paleoanthropology generally, is working to achieve parity. The journal is likely to soon introduce a double-blind review process, which has been demonstrated to reduce bias and increase equal opportunity by gender as well as ethnicity, nationality, and seniority.

Major Impact

The number of papers received has increased steadily, with 306 submitted and 104 published in 2016; for 2015 the numbers were 283 and 150. The rejection rate in 2016 was almost 60%, but JHE has a tradition of working with authors to assist revision so that many "rejected" articles are actually published after reworking. In 2016, the average time from submission to acceptance was

47 weeks, to a citable online publication about 14 months and another 5–6 weeks to print copy. The majority of articles concern Plio-Pleistocene hominins and archeology, but there is also strong representation from primate morphology, primate evolution, geology and related fields, and the behavior of living primates. About 42% of 2016 published articles have corresponding authors from North America and 34% from Europe. At 3.932 (for 2015), the journal has the second highest five-year impact factor of any journal in Anthropology, in the top third of all journals in the Evolutionary Biology group, and there were over 436,000 downloads of articles in 2016.

Journal of Material Culture

Andrew Thomas Wilkinson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Brief Definition of the Topic

The *Journal of Material Culture* is a peer-reviewed publication that ranks highly in the field of cultural studies (2011 Journal Citation Reports 2012). Material Culture is a term used to describe the physical components in cultural studies. Objects made or modified through human behavior are considered an important source for archaeological interpretation. Knowledge gained from the study of artifacts and their social identity requires the application of theoretical models and sound methodologies. The *Journal of Material Culture* encourages an interdisciplinary approach to examine the associations between artifacts and social relations, "...irrespective of time or place" (Aims and Scope 2013). These relationships are considered important to the understanding of cultural construction and practice.

To go beyond established disciplinary limits, the *Journal of Material Culture* aims to "...promote and develop a general comparative and international perspective by publishing papers on theory and methodology, interpretive strategies and substantive studies of key themes and issues" (Aims and Scope 2013). Academic specializations include anthropology, archaeology, design studies, history, human geography, museology, and ethnography.

First published in 1996, the *Journal of Material Culture* is a quarterly production. The journal is supported by a global board of editors under the editorial management of Ludovic Coupaye and Adam Drazin, both from the University College of London, United Kingdom. The *Journal of Material Culture* is published by SAGE Publications as a printed and electronic work and is available by subscription or online at http://mcu.sagepub.com.

Journal of Social Archaeology

Lynn Meskell
Department of Anthropology, Stanford University, Stanford, CA, USA

Brief Definition of the Topic

The *Journal of Social Archaeology* (JSA) is a fully peer-reviewed international journal covered in the ISI Arts and Humanities Citation Index. The journal promotes interdisciplinary research focused on social approaches in archaeology, opening up new debates and areas of exploration. It engages with and contributes to theoretical developments from other related disciplines such as feminism, postcolonialism, social geography, literary theory, politics, anthropology, and cognitive studies. JSA is explicitly global in outlook with temporal parameters from prehistory to recent periods. As well as promoting innovative social interpretations of the past, it also encourages an exploration of contemporary politics and heritage issues.

The idea of journal devoted to social approaches in archaeology developed in 1998, and the first issue was published in 2001. The editorial panel includes high-profile archaeologists, as does the larger advisory board which also features leading figures in the humanities and social sciences. The constitution of the board reflected the journal's aims for global coverage and a full temporal scope from the deep past to the contemporary world, linking past and present, the local and the global.

JSA encourages papers from a variety of theoretical perspectives, being inclusive and innovative rather than policing the boundaries of a single academic position. At its inception, one particular aim was to break the divide that then separated American and European archaeology, and this was also reflected in the composition of the editorial panel as well as the scope of the papers and interviews solicited in the early issues. It was generally felt that archaeology had experienced a rather dull patch since the mid-1980s, and it would be particularly timely to challenge the current status quo, by being openly theoretical, interdisciplinary, and global, and blurring the boundaries between British and North American traditions. But it would also encourage theoretical and social approaches from other national and regional traditions: Latin America, Australasia, the Middle East, and South Asia.

Looking back a decade later in 2011, clearly archaeology is changing: our networks, collaborations, and the perceived centers of expertise have shifted considerably since the 1990s. Many of today's most exciting directions in archaeology are not necessarily generated in either Britain or the United States or by debates over what constitutes good science or good theory. Some of the most exciting work to come out of JSA has been conducted by Spanish, South African, Swedish, Colombian, Greek, and Australian archaeologists.

The journal has attempted to foster intradisciplinary exchange by bringing together widely separated discourses and traditions. Regional specializations are now subject to wider global dissemination. The journal aims to break down those arbitrary and hegemonic boundaries between North American, Classical, Near Eastern, Mesoamerican, European, and Australian archaeologies, for example. Typically these regions are never considered together. Egyptologists, Classical archaeologists, and Mesoamericanists each have their own narrow journals. JSA thus provides a forum in which archaeologists working on common issues in different areas can engage with each other over questions of theory. The central requirement of all published work is that a serious attempt is made to engage the social as not merely epiphenomenal but central to an understanding of past and present identities and meanings.

JSA represents a major effort to combine a host of theoretical orientations, diverse time periods, and geographical areas and bridge the divide between American and British archaeologies. Just as predicted in the first editorial for JSA in

2001, we have gone on to publish a suite of different contributors from Bangladesh, Iran, Zimbabwe, Australia, Turkey, Brazil, Palestine, and Cuba. Social topics published have included sociopolitics, identity, gender, postcolonialism, representation, landscape, mortuary studies, ritual, household studies, and material culture, among others.

The challenge for social archaeology is to be committed to understanding past societies in terms of their social contexts and lived experiences while, at the same time, to remain cognizant of how the knowledge of the past that we produce is used in the present. One avenue to accomplish this goal is to move from conceptualizing society as an object to thinking of society in terms of social relations that constitute the core of any analysis. Archaeologists can then examine how material culture is continuously implicated in webs of signification in the processes of creating meaning.

Reflecting on the first decade of JSA, it is striking to see the enormous diversity of articles published to date and the balance of exciting young scholars, many still students, combined with very established figures in the field. There has also been remarkable disciplinary scope in journal submissions that engage with linguistics, genetics, chemistry, art, philosophy, ethnography, and ethics. This is very much in keeping with our original editorial mission crafted in 2001 to situate archaeology within wider discourses across the humanities and the social and natural sciences.

We can now track the changing landscape of social archaeology. While the 1990s were so concerned with issues of identity, agency, and landscape, today there is a greater emphasis on heritage ethics, archaeological responsibilities, and multidisciplinary fieldwork. This is not to say that social archaeology has jettisoned its mainstream focus on spatiality, materiality, embodiment, biography, ritual, and difference. On the contrary, JSA has featured numerous articles devoted to architecture, memory, phenomenology, power, and practice that attest to the vibrancy of these topics and the new ways in which they are being explored. In the last decade single issue polemics have been replaced, in the main, by more complex and multistranded analyses. Rather than simply targeting ethnicity or gender, for example, recent archaeological work aims to embrace a wider set of social determinants in the lives of historically situated individuals by pursuing multiple lines of inquiry.

The journal remains committed to a very broad remit that includes our understandings of the deep past, contemporary archaeological practice, and engagements with the recent past.

Joyce, Rosemary

Robert W. Preucel[1] and Julia A. Hendon[2]
[1]Department of Anthropology, Brown University, Providence, RI, USA
[2]Department of Anthropology, Gettysburg College, Gettysburg, PA, USA

Basic Biographical Information

Rosemary Joyce (Fig. 1) is a prominent anthropological archaeologist widely known for her work on the archaeology of gender, sexuality, and embodiment, based on visual culture of pre-Columbian Central America. Born in Buffalo, New York, in 1956, she was the sixth of eight children of Thomas Joyce, a steelworker, and Joanne Poth Joyce, a homemaker. Joyce was educated at the Mount Saint Joseph Academy. She received her bachelor's degree in 1978 from Cornell University and her doctorate in anthropology from the University of Illinois at Urbana-Champaign in 1985 studying under David

Joyce, Rosemary, Fig. 1 Rosemary Joyce. (Photo by Russell Sheptak)

Grove. She is married to the ethnohistorian and archaeologist Russell Sheptak, with whom she has collaborated on many research projects.

Joyce was appointed Assistant Curator of pre-Columbian Archaeology at the Peabody Museum, Harvard University, in 1985, and made Assistant Director in 1986. Concurrently, she held the positions of Assistant and Associate Professor in the Department of Anthropology. In 1994, Joyce was hired as the Director of the Phoebe Hearst Museum of Anthropology (1994–1999) and as an Associate Professor of Anthropology at the University of California, Berkeley. She was promoted to Professor in 2001 and served as Chair of the Department (2006–2011). She was appointed the Richard and Rhonda Goldman Distinguished Professor in the Social Sciences in 2009 and made the Associate Dean for Social Science, Graduate Division in 2011.

Joyce is the recipient of many national fellowships and honors. She has held a Bunting Institute Fellowship at Radcliffe College, Harvard University (1992), University of California Humanities Research Institute Fellowship (1999), and a Center for Advanced Study in the Behavioral Sciences Fellowship at Stanford University (2001). She was selected as the Distinguished Lecturer by the Archaeology Division of the American Anthropological Association in 2003. She served as President Elect (2009–2011) and President (2011–2013) of the Archaeology Division. She was awarded a John Simon Guggenheim Memorial Foundation grant (2010) to study the history of Central American collections in European museums. Most recently, she was appointed by President Obama to the Cultural Property Advisory Committee of the US Department of State in 2011.

Major Accomplishments

A self-described field archaeologist who has carried out survey and excavations at sites spanning the full range of pre-Columbian and Colonial period occupation in Honduras since 1977, Joyce has made important contributions to practice-based theoretical approaches to interpreting the archaeological record. Her commitment to theoretical advancements that are solidly grounded in empiric data has resulted in a series of studies that not only advance understandings of issues of gender, embodiment, materiality, and agency but also contribute new ways of studying the material record.

In her book, *Cerro Palenque: Power and Identity on the Maya Periphery* (1991), she introduces the idea of an "archaeological ethnography," or "archaeography," to account for the dual project of archaeology – the observation of material remains in order to make inferences about the past and the construction of written accounts of the past based upon these observations. For her, archaeological ethnographies have the same epistemological status as interpretations as standard cultural ethnographies. Although they are dependent upon observations of material culture patterning rather than behavior, they share the goal of explicating culture defined as those meanings specific to a particular time and place.

Joyce was one of the first archaeologists to consider women and more broadly gender as legitimate topics in Mesoamerican archaeology. Her initial focus was on the contrast among three lines of evidence: the representation of women in Maya monumental art, the representation of gendered activities in small-scale representations such as figurines, and the presence or absence of women in the ethnohistoric documents (Joyce 1993, 1996). Her analyses led her to argue that although gender was a definite part of

differentiation within Mesoamerican societies, the kinds of difference created were not (or not only) hierarchical in some simple framework. Thus, men and women were often shown in complementary forms of action, and the kinds of action that gendered figures engaged in differed depending on social location (at home, in public) and in terms of social class. In a careful effort to distinguish between representation and actual practice, Joyce has contrasted and compared burial practices with artistic representations. In an important reanalysis of the burials from Tlatilco, a Central Mexican Formative period site famous for its rich burial offerings in a household context, Joyce (2001b) not only highlighted the care with which women were buried but used the distribution of burials to argue for continuity over time in kinship and social relations.

Drawing on the work of Judith Butler, Joyce (1998, 2001a) views gender and sex as socially constructed and shaped. This led her to a concern with embodiment, in which a real, corporeal body is nevertheless understood not as some natural entity but as something shaped, even sexed, by social and cultural views. Joyce (2005) has argued strongly that bodies are better understood as sites of lived experience than as appearances or images to be "read." She and Lynn Meskell have demonstrated the value of this approach, which emphasizes habitual actions and dispositions as much as image, ornamentation, or representation (Meskell and Joyce 2003). Her analysis of Playa de los Muertos figurines, produced in Honduras during the Formative period, exemplifies the value of her approach (Joyce 2003, 2008). Through a detailed examination of the depiction of gestures, hairstyles, size, and other factors, Joyce argued that the female body (these figurines are all of women) was a site of display and modification that reflected socially constructed identities that were both personal and social, tied not only to gender but to age as well.

Joyce is particularly interested in the semiotics of representation. In her book *The Languages of Archaeology: Dialogue, Narrative, and Writing* (Joyce 2002), she offers a critical study of the rhetorical practices archaeologist use to create representations of the past. Central to her study is a critical engagement with the dialogic model of the literary theorist Mikhail Bakhtin. This model emphasizes the concepts of heteroglossia and polyphony or multivocality as a means of textual interpretation. Joyce suggests that these concepts can be used to clarify questions of how and why multivocality is typically suppressed in the writing of archaeological narratives and why it matters that archaeologists attempt to recapture multivocality in the construction of archaeological knowledge. She suggests that thinking about the perspectives of multiple actors in the past as well as multiple audiences in the context of experimental writing offers a new opportunity to go beyond the constraints of disciplinary boundaries and standard notions of time-space relations.

As evidenced by her theoretical interests, Joyce is a committed anthropological archaeologist. She helped organize an American Anthropological Association panel that resulted in a special publication entitled *Archaeology is Anthropology* (Gillespie et al. 2003b). As she notes, in her concluding chapter (Gillespie et al. 2003a), it is possible to turn around the question of archaeology is anthropology or it is nothing, to ask "what kind of anthropology is archaeology." This shifts the issue away from tedious disciplinary debates to a concern for archaeological theory building and practice. She concludes that whether or not archaeology formally splits off from anthropology, it will remain anthropological because it is integrative and concerned with the big questions of who we are, where we came from, how we got here, and where we are going.

Joyce's research is characterized by the focus on people's engagement with the material world at multiple social scales, from that of the individual body, the household, the community, and the larger landscape which these groups inhabit. Her interest in these issues has allowed her to develop a far more nuanced picture of Mesoamerican social relations even as it has led her to propose ways of interpreting the past of interest to scholars across the discipline.

K

Kakadu National Park: Rock Art

Sally Kate May and Paul S. C. Tacon
PERAHU, School of Humanities, Griffith University, Gold Coast, QLD, Australia

Introduction

Kakadu National Park, located in the top end of the Northern Territory of Australia, covers 19,804 km^2 of diverse tropical ecosystems. This vast area includes mangroves, mudflats and floodplains, major rivers, savanna woodlands, monsoon forests, sandstone escarpments, and rocky plateaus. Most importantly, Kakadu is an Aboriginal living cultural landscape. There are many different clan groups within Kakadu with each caring for their "country" and sharing in joint management of the park with the Commonwealth Government of Australia. Kakadu is universally acknowledged as one of the world's great rock art provinces. Internationally recognized through UNESCO World Heritage List for both its cultural and natural heritage, Kakadu has one of Australia's largest concentrations of rock art sites. Rock art played a vital role in Kakadu, achieving World Heritage status, with particular mention made of the antiquity, concentration, temporal span, and diversity of the art as well as its links to continuing cultural traditions (Fig. 1).

Key Issues

Characteristics

It is estimated that there are over 15,000 rock art sites of varying ages within Kakadu. While this is only a fraction of Australia's rock art, sites contained within Kakadu represent a highly significant and diverse suite within a protected national park. The rock art is overwhelmingly paintings; however, stencils also feature heavily. Less frequent are prints, engraved motifs including cupules, and beeswax figures pressed onto the rock surfaces. Paintings, stencils, and prints are made using natural ochers and white pipe clay sourced locally and traded across Kakadu and neighboring regions. In the late 1800s and early 1900s, Reckitt's Blue washing powder was occasionally used to depict traditional and new subject matter.

Chronology

Rock art dating is one of the biggest challenges in rock art research so few images have been directly dated. Consequently, we do not know how old much of the art is, but there is a range of evidence to suggest that the oldest surviving rock art,

Kakadu National Park: Rock Art, Fig. 1 Most rock art in Kakadu adorns the surfaces of open-air rock-shelters rather than cave systems such as those in Spain or France

including paintings of large naturalistic animals, is over 15,000 years of age and possibly as much as 30,000 years. G. Chaloupka has argued some rock art could be even older and that Kakadu has "the world's longest continuing art tradition" (Chaloupka 1993: 15). Certainly, the rock art illustrates significant environmental, technological, and stylistic change over time, and a number of sequential styles have been identified in the art by studying the superimposition of individual paintings and comparing this across many hundreds of sites so far studied (see, e.g., Lewis 1983, 1988; Chaloupka 1984, 1993; Figs. 2 and 3). These studies have largely used the depiction of extinct animals and a wide variety of artifacts, clothing, and recent subject matter to mark the changes in style from the pre-estuarine, estuarine, freshwater, and historic periods (Figs. 4 and 5).

Research

The first record of rock art in (what is now known as) Kakadu was made by explorer Ludwig Leichhardt in 1845; however, it was not until the 1960s that rock art studies gained some momentum. The earliest work was undertaken by W. Arndt (1962) with his published interpretations of paintings at three sites. In the late 1960s, J. Jelinek (1978) carried out intensive recording of the Ubirr sites during the Czechoslovakian Expedition to Arnhem Land. These fleeting studies were then followed by more significant work in the late 1960s and 1970s, largely concentrating on artistic styles and establishing relative chronologies. E. Brandl (1968, 1973) was the first to systematically analyze the rock art of the region through an examination of changes in technology reflected within superimposed motifs.

The most widely recognized rock art recorder (and key advocate for the protection of rock art in Kakadu) was G. Chaloupka who, in 1984, produced a stylistic chronology of the Arnhem Land plateau rock art that incorporated four broad artistic periods: pre-estuarine, estuarine, freshwater, and contact (Chaloupka 1984, 1985). He defined the sequence by combining the evidence of superimpositions, differential weathering, defined

Kakadu National Park: Rock Art, Fig. 2 The changing environment of this region is reflected in the rock art of Kakadu

Kakadu National Park: Rock Art, Fig. 3 Stencils of material culture (such as this boomerang) can be found across Kakadu and help to fill gaps in our understanding of materials that do not survive in the archaeological record

Kakadu National Park: Rock Art, Fig. 4 Paintings of extinct animals such as the thylacine (Tasmanian tiger) provide important clues as to the age of rock art in Kakadu

Kakadu National Park: Rock Art, Fig. 5 One of the most common subjects in Kakadu rock art is fish and other animals depicted with internal organs showing (x-ray)

styles, and changes in the range of depicted animal species and their environmental contexts. This work both expanded upon and departed from Brandl's earlier work. Chaloupka believed the key to major stylistic changes was significant environmental change, particularly sea level fluctuations, experienced in the region during the late Pleistocene and early Holocene.

The late 1970s and 1980s saw a peak in the level of rock art and archaeological research occurring within Kakadu, associated both with mining exploration and the establishment of Kakadu as a national park and World Heritage site. This included research by D. Lewis (1977, 1983, 1988), P.S.C. Taçon (e.g., 1987, 1988, 1989a, b), J. Jelinek (1989), and R. Gunn (e.g., 1987). Throughout the 1980s, G. Chaloupka, R. Gunn, I. Haskovec, and H. Sullivan undertook a number of cultural surveys within the park which included community consultation (e.g., Chaloupka et al. 1985; Chaloupka and Kapirigi 1981; Gunn 1987; Sullivan and Haskovec 1986, 1987, 1988). These reports, as well as Taçon's Ph.D. thesis (1989b) and related publications, contain important ethnographic information relating to rock art and rare firsthand accounts from Aboriginal rock artists.

Collaborative rock art research continued in the early 1990s, particularly by Tacon (e.g., 1992, 1993 and with Chippendale and Taçon 1993, 1998; Taçon and Chippendale 2001, 2008; Taçon et al. 1996), Gunn (1992), and Chaloupka who in 1993 published "Journey in Time: the World's

Longest Continuing Art Tradition." This detailed publication provides a summary of his extensive research into the art sequence of Kakadu over the preceding decades. Since the mid-1990s, the level of rock art research occurring throughout Kakadu National Park has largely declined. Some Aboriginal people in Kakadu felt overrun by archaeologists and rock art researchers and desired to better control access to their country and to participate more equally in the documentation of sites for management (KCHS 2012).

As a result new collaborative research programs emerged in the early to mid-2000s including those run by the Jawoyn Association and Gundjeihmi Aboriginal Corporation. Parks Australia (Kakadu) cultural heritage staff also run a rock art management and conservation program and collaborate with rock art researchers as part of this program.

Continuing Artistic Traditions

For local Aboriginal people, rock art is just one part of a much wider and more complex cultural system that interweaves land, cultural law, other art traditions, ancestral beings, people, and other creatures. While we may try to ease our understanding by separating out the strands, in essence, one component of "culture" cannot be fully understood without the others. Some rock art imagery is intimately linked with ceremony, other designs to storytelling, and training in cultural law. Many sites simply relate to the everyday activities of past and present men, women, and children. The role that rock art plays in Aboriginal cultures is best described by local Aboriginal people, and information should only be shared in line with cultural protocols determined by different clan groups within Kakadu.

The rock art of Kakadu National Park is one of the world's great treasures, an immense source of pride for local Aboriginal groups and an irreplaceable resource for understanding Australia's past.

Kanaseki, Hiroshi

Makoto Tomii
Centre for Cultural Heritage of Kyoto University, Kyoto, Japan

Basic Biographical Information

Hiroshi Kanaseki is a Japanese archaeologist and an Emeritus Professor of Tenri University (Fig. 1). He was born in Kyoto in 1927 as the second son of the famous anthropologist, Takeo Kanaseki. Takeo learned archaeological methodology at Kyoto University from Kosaku Hamada, who is regarded as the father of archaeology in Japan, while he worked as an Assistant Professor of the Department of Anatomy of the university. Takeo Kanaseki submitted a doctoral thesis on the anthropological study of Ryukyu people in East Asia, three years after Hiroshi was born, and then moved to Taipei to become a Professor of the former National Taiwan University. Hiroshi Kanaseki joined his father on the island in 1936. During his teenage years in Taiwan, Hiroshi often accompanied his father to help at archaeological excavations.

After returning to Japan in 1946, Hiroshi Kanaseki finished the science course in Matsue High School (in the old system of education, equal to the half stage of undergraduate studies in the present educational system) and then started studying archaeology at Kyoto University. The main material that he investigated at that time was Chinese bronze objects of the Warring States

Kanaseki, Hiroshi, Fig. 1 Hiroshi Kanaseki (*left*) with Claire Smith and Katsu Okamura at WAC Inter-Congress, Osaka, January, 2006. (© Hidetaka Bessho)

period. In 1953, he received his Bachelor of Arts from Kyoto University. In 1956, after several years of postgraduate study, he became an assistant specializing in drawing archaeological materials at the Nara National Research Institute of Cultural Properties. During his time at the Institute, Hiroshi Kanaseki joined in the excavations of cemeteries of the Yayoi period in Western or Southern Japan, including Doigahama and Hirota, where considerable data was collected on prehistoric mortuary practices. In addition, he excavated some of the oldest Buddhist temples, dating to sixth century CE, in and around Osaka, including Asuka-dera and Shiten'no-ji.

From 1959 Hiroshi Kanaseki worked as a member of the academic staff of Tenri University, and from 1965 onwards he started his expeditions of archaeological research in Israel. In that same year, he was asked to direct a large-scale excavation of a Yayoi village in Osaka, named Ikegami-Sone. Following his contribution to this excavation and continual advice of wisdom for the local government which succeeded to conduct the series of excavations there, Hiroshi Kanaseki asked to be the Director of the Osaka Yayoi Museum (1991–2012), which is built beside the traces of what is assumed to be large shrine of Ikegami-Sone site. In 1992, he founded the Department of Archaeology at Tenri University, which included study of the discipline of folklore. He retired the university in 1997.

Professor Kanaseki played a key role in the internationalization of Japanese archaeology through his support for the World Archaeological Congress' Inter-Congress of the topic of "Kyosei-no-koukogaku: Coexistence in the Past – Dialogues in the Present," which was held in Osaka in January, 2006. In 2013, his contribution to world archaeology, particularly to breaking down barriers between archaeology in Japan and in the outside world, was recognized when he received the Inaugural President's Award of the World Archaeological Congress.

Major Accomplishments

Professor Kanaseki became very experienced in excavation during his stay in Taiwan with his father. This attracted him so much as to lead him to the discipline of archaeology. Moreover, since his childhood, the wide range of acquaintance with leading scholars basically through his father's connections continued to help him to accumulate his immense knowledge on ancient human life. However, his considerably broad

knowledge of archaeology and its surrounding disciplines within the global scale emerged in the latter half of his career in archaeology. For example, while he worked as a Professor at Tenri University, he was involved with so-called Biblical archaeology in Israel, contributing to excavations at Tel Zeror and directing excavations at Ein Gev. This research seems to have made him consider the relationships between archaeological activities and the religious and political aspects of the modern world.

Professor Kanaseki's research has provided much insight into religious beliefs in the prehistoric and protohistoric periods in Japan, but his chief concern lies with the Yayoi period, the time when domestication was first introduced, from the early first millennium BCE to the third century CE. He has tried to increase the systematic understanding of Yayoi culture by paying more attention to the aspect of past beliefs, the subject of which has been almost untouched among most Japanese archaeologists because of the difficulty to approach this topic. Professor Kanaseki has researched a range of archaeological materials such as figurines, images drawn on objects, and grave goods and used a range of information sources from literature and folklore. One of the outstanding results of his investigation is his discussion of bird spirit worship, based on his analysis of wooden bird objects found at Ikegami-Sone. Professor Kanaseki argues that this belief was introduced in the Yayoi period along with agricultural practice and that it derived from the ancient Chinese civilization. He says that the essence of archaeology is not only to examine materials and analyze data but also to create something new that arises from the integration of past materials and the mind.

Professor Kanaseki's erudition and extensive knowledge together with his affectionate nature have allowed him, for a long time, to supervise various projects relating to ancient cultures, to organize many symposia and academic meetings, to edit a number of books, and to be invited to be the Director of a number of museums. The standing of his contributions to international archaeology is recognized in the Inaugural President's Award of the World Archaeological Congress.

Kantman, Sönmez

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Sönmez Kantman was born in İstanbul in 1940. He died in 1999. He got his degree from Robert College, Istanbul. Afterward, he studied law in Switzerland and then continued his education in the Department of Protohistory and Near Eastern Archaeology at İstanbul University, Turkey.

Kantman was a Renaissance scholar with wide-ranging interests. Besides his scientific research, he was interested in art studies and literature. He wrote a play in French, named *Patira*, and he translated thirteenth century Japanese haikus into Turkish in preparation for a book called *Kokinşiu*.

He participated in excavations and survey studies early in his career, but in his later career concentrated his research efforts on the theory of practicing archaeology. His book *Analytic Archaeology* is a result of this research.

Major Accomplishments

Sönmez Kantman's name is on the verge of being forgotten. However, he should be remembered and honored for his remarkable study *Analytic Archaeology* which he coauthored with Ali Dinçol.

In the 1960s, around the world, the social sciences stream was strongly influenced by developments in new approaches and thinking systems. In the field of archaeology, new concepts such as archaeometry and processual archaeology were much discussed by academics. In Turkey, two young researchers Sönmez Kantman and Ali Dinçol who were in their early 20s undertook a study of both theoretical and practical methods in archaeology. This study emerged to contest the excavation-based archaeological tradition in Turkey. Kantman and Dinçol aimed to generate a discussion about the problems of practicing archaeology in Turkey and to offer a systematic approach to archaeological theory and method. Their interdisciplinary work was published under the title of *Essays on Analytic Archaeology*.

However, their work was ignored by the conservative structure of academy. After this, Sönmez Kantman gave up his career in archaeology and continued his career in a completely different field, while Ali Dinçol became a philologist.

However, their work had a significant impact on the next generation of archaeologists, suggesting avenues for research that are beyond the normal focus on excavations. While Sönmez Kantman and his work *Analytic Archaeology* did not find the response that they deserved at the time the work was published, this volume did open up a new area of discussion area and encouraged young researchers to generate new ideas that went beyond the traditional focus on excavations in Turkish archaeology.

Karstic Landscapes: Geoarchaeology

Andrea L. Balbo[1] and Eneko Iriarte[2]
[1]Centre for Earth System Research and Sustainability (CEN), University of Hamburg, Hamburg, Germany
[2]Laboratorio de Evolución Humana, Departamento de Ciencias Históricas y Geografía, Universidad de Burgos, Burgos, Spain

Introduction

Karstic landscapes are found over 12% of the Earth's terrain. Due to their physicochemical (e.g., high alkalinity) and physiographical (e.g., caves, dolines, poljes) characteristics, they preserve some of the most impressive evidence of human evolution and behavior as well as good continental paleoenvironmental records. It is perhaps due to these reasons that karstic landscapes have seen some of the earliest applications of geoarchaeology (e.g., at the Haua Fteah cave in McBurney 1967). In spite of recent attempts (e.g., Reeder 2011), a full overview on the geoarchaeology of karstic landscapes that goes beyond the study of caves is still missing in textbooks and review articles. The need for a more comprehensive definition and systematization is apparent from the rising number of dedicated conference papers and publications and the integration of geoarchaeology in research clusters and institutes focusing on the interdisciplinary study of karstic landscapes. The present contribution thus aims at drafting a broader definition of this potential branch of archaeological and paleoenvironmental research, stemming from scientific archaeology, environmental archaeology, and human ecology, in view of possible future developments.

Definition

The broad geographical distribution of karstic regions, together with the potential they show for archaeological preservation, means that they have provided much evidence to virtually all the current relevant questions in archaeology and human paleontology. In this sense, a definition of the geoarchaeology of karstic landscapes needs to be made in the broadest possible sense, especially concerning its resolution in terms of the scales of approach and methods implied. Thus, the geoarchaeology of karstic landscapes is no different from geoarchaeology as a whole, in that it contributes to issues related to both human-environment interaction and archaeological site formation and preservation, employing a hybrid multi-scalar methodological and theoretical framework with contributions from archaeology and the geosciences. However, geoarchaeological applications in karstic regions need to take into account the peculiarities of such landscapes in terms of their origin, distribution, taxonomy, and taphonomy.

Karstic regions offer the possibility for geoarchaeological applications in two main contexts, namely, subterranean and surface karst (Fig. 1). Cave deposits preserve long sequences of human occupation where micromorphology and microarchaeology find some of their most fruitful applications. As for paleoenvironmental reconstructions within caves, the isotopic study of speleothems currently offers some of the records with highest resolution. As for surface karst, superficial wetlands offer the best-preserved and more continuous sedimentological sequences with preserved proxies for paleoenvironmental reconstructions and for studying trajectories of long-term interaction between humans and this particular kind of landscape. While archaeological preservation is often poor in surface karst, the study of the distribution of surface archaeological evidence in connection with regional physiographical traits (through remote sensing, geomorphology, pedology) is key to understanding human occupation strategies and impact within these environments.

Origin and Distribution of Karstic Landscapes Worldwide

The solid geology of most of our planet (c. 70%) is made of highly soluble sedimentary

Karstic Landscapes: Geoarchaeology, Fig. 1 Examples of geoarchaeological contexts in surface and subterranean karstic landscapes. (**b**) Neolithic coastal site near Liznjan in Southern Istria (Croatia) being eroded away by Holocene sea-level rise. (**c**) Sampling speleothems at Cova Murada, Menorca. A megalithic Bronze Age wall used to close the entrance to the cave, where dozens of burials were excavated in the early twentieth century. (**d**) Cyrene (Libya, UNESCO World Heritage site since 1982), a Greek colony of Thera founded in 630 BCE, romanized in 74 BCE. The photographs show the damages of an earthquake on the bathing quarters of the city known as the *Aqua Augusta*. Classic writers attest two major earthquakes affecting Cyrene in CE 262 and in CE 365

calcareous rocks, such as limestone, dolomite, and aragonite, formed at the bottom of the sea during different geological periods (Ford and Williams 2007). Karstic landscapes are formed within these carbonate geological formations through meteoric dissolution, a process referred to as karstification. Across latitudes karstic regions give origin to contrasting landscapes (from barren ground to rain forest) in different climatic zones (from circumpolar to temperate and tropical).

The distribution of karstic regions, from Malaysia to Cuba and from Alaska to New Zealand (Fig. 2), makes them most

Karstic Landscapes: Geoarchaeology, Fig. 2 Karst regions of the world. Available at http://www.circleofblue.org/waternews/2010/world/chinas-karst-region-infographics/. Accessed 22 May 2012

interesting for archaeologists and human paleontologists. Karstic landscapes are often distributed along tectonically active regions (e.g., Alpine and Himalayan systems). In addition, karstic regions coincide with some of the main intercontinental corridors and bridges (e.g., Sinai, East Africa, Indonesia, Central America). As a result, karstic regions are ideal places for studying trends in human evolution and dispersal. Besides, they show some of the highest concentrations of human population, past and present (e.g., Egypt, Mesopotamia, North and Northwest India).

Taxonomy of Karstic Landscapes

Most karstic features and landscapes were first observed in SE Europe, and their geomorphological definition derives often from Slavic languages. Karst is the German modification of the Croatian word *krš* (rock). In common language, the word was originally employed to indicate the bare stony ground of the limestone regions of western Slovenia. The term karst has now become part of the geomorphological lexicon to define a "terrain with distinctive characteristics of relief and drainage, arising primarily from a higher degree of rock solubility in natural waters than is found elsewhere" (Jennings 1971: 1).

Karstic landscapes may be classified into two major groups, each generating a variety of landforms: surface and subterranean (Ford and Williams 2007). Surface landforms (exokarstic) include dissolution features such as poljes, karrens, dolines, sinkholes, cenotes, bridges, and towers. Due to the high permeability of carbonate rocks, surface karstic landscapes are characterized by low water retention and scarce surface waterways. In surface karstic landscapes, most water penetrates rapidly through sinkholes or diffusely through the permeable calcareous bedrock generating extensive subterranean drainage systems and a variety of subterranean landforms (endokarstic), mostly vadose and/or phreatic conduits of different scale, caverns, and caves.

Taphonomy of Karstic Landscapes

Despite being by definition more easily accessible, surface karstic landforms have received much less attention in archaeological and geoarchaeological research than subterranean ones. This is mainly due to the "aggressiveness" of the soils and sediments found on surface karstic landforms. The high alkalinity (low pH) of carbonate rocks and derived soils, combined with weathering, leads to the rapid dissolution of bone collagen and organic materials in surface

karstic landforms. Even phytoliths, among the most resistant plant fossil remains, suffer from higher dissolution rates in archaeological assemblages from surface karstic landforms, where lithic remains are often the only evidence preserved (Andel and Runnels 2005). However, in specific cases, past surface karstic landforms (e.g., paleosoils, limnic deposits, fluvial sequences) have been preserved within karstic depressions, buried under later alluvial, colluvial, and anthropic deposits, or in waterlogged conditions. In such cases, preservation of paleoenvironmental proxies in sedimentary sequences and anthropic features in archaeological contexts has been maintained (e.g., Siart et al. 2010; Palomo et al. 2011). Geoarchaeology can therefore be applied in exokarstic landscapes in both archaeological and non-archaeological contexts, providing an insight into human-environment interaction and past socio-ecological systems. Archaeological deposits provide evidence relative to the use of surface karstic environments for settlement and sustenance, while sedimentary sequences provide information relative to environmental change at the local, regional, and global scales (Balbo et al. 2006; Balbo 2009; Iriarte et al. 2011).

Subterranean karstic landforms have been a critical source of archaeological and geoarchaeological information worldwide (Rapp and Hill 1998; Goldberg and Macphail 2006). Caves and rock-shelters provide a protected environment and have been occupied throughout human history for different activities. Endokarstic landforms show much less diurnal and seasonal variation in terms of moisture and temperature than exokarstic ones. In addition, caves and rock-shelters favor burial, increasing the potential for preservation. In some exceptional cases, e.g., when cave entrances have been sealed rapidly after human occupation, materials as fragile as human hair have been found (e.g., Bronze Age deposits found at Cova d'es Càrritx, Menorca, in Wellman 1996). Although artifacts and fossil accumulations may be preserved, taphonomic histories of these types of deposits are often complicated. Site formation processes are eclectic due to the characteristics of the bedrock and the complicated depositional, erosional, and occupational processes involved. Both clastic and chemical depositions occur. Clastic deposits include debris produced by human and animal occupation, washes, fluvial, and aeolian deposits, as well as rockfalls. The most common chemical precipitates are calcite depositions such as flowstone or dripstone. While preserved from weathering, bone deposited in karstic caves is exposed to calcification, often resulting in poor collagen preservation. Exceptional situations exist where good DNA preservation has permitted a first sequencing of the Neanderthal genome (Green et al. 2010). As a result of such taphonomical advantages and limitations, cave stratigraphies constitute intriguing depositional systems. They have played an important role in archaeology, and they are still a critical source of chronostratigraphic and artifactual data. Again, in these contexts geoarchaeology may contribute in terms of understanding human-environment interaction based on a combination of evidence from archaeological deposits and specific sedimentary features such as stalagmites, providing high-resolution paleoenvironmental information through isotopic analysis (McDermott 2004).

Key Issues/Current Debates

Archaeology of Karstic Landscapes

Karstic landscapes worldwide are intertwined with major questions in archaeology and human paleontology including human origins and dispersal, human environmental behavior, and the emergence of early civilizations.

Human Origins, Evolution, and Dispersal

Karstic caves have provided key archaeological and paleontological evidence of hominin and modern human origins, evolution, and dispersal. Some of the most spectacular discoveries of hominin fossils were made in the past decades in the karstic landscapes of the South Cape province, South Africa, e.g., at Sterkfontein, Swartkrans, and Kromdraai (Martini and Kavalieris 1976; Dirks et al. 2010). Zhoukoudian cave in China gave one of the earliest examples of hominin presence in Asia 1 Ma (Goldberg et al. 2001). The karstic complex of Atapuerca offers

the most continuous fossil record of Europe with dates ranging from c. 1.5 Ma virtually to the present day (Carbonell et al. 2008). Blombos Cave in the South Cape province (South Africa) has provided some of the earliest fossils and artifacts attesting to the origin of anatomically and behaviorally modern humans (AMH) before 100 ka (Fisher et al. 2010; Henshilwood et al. 2011). The worldwide dispersal of AMH has been documented in karstic caves and landscapes in Israel (e.g., the disputed case of the Qafzeh in Niewoehner 2001), Borneo (Niah Cave in Barker et al. 2007), and SE Alaska, where karstic caves bear evidence of AMH migration into the American continent crossing the Laurentide Ice Sheet (Dixon et al. 2001). Karstic islands and wetlands have also offered evidence concerning the role of boats and seafaring for human dispersal and the spread of agriculture (Marangou 2003; Papageorgiou 2009). The demise of Neanderthals in Europe (e.g., Gibraltar in Finlayson et al. 2006) and their possible presence in Africa (e.g., Benzú in Ramos et al. 2008) have also been the subject of extensive archaeological research in karstic landscapes. More recently, findings from the Island of Flores, Indonesia, question the lone existence of AMH on Earth since the extinction of Neanderthal. Fossils of *Homo floresiensis* found in tropical karstic caves provide evidence of karstic landscapes supporting species other than our own as late at 15 ka (e.g., in Aiello 2010).

Human Environmental Behavior

A large proportion of rock paintings and carvings have been found in karstic caves. Similarly, numerous portable decorated objects have been found in karstic caves and in surface karstic landscapes. Such depictions of zoomorphic and human figures as well as plants offer evidence of the fauna and flora that characterized karstic environments before their extensive transformation through intensive hunting, domestication, and urbanization. Examples of rock art and portable art in karstic landscapes include Altamira (Valladas et al. 1992) and Fumane (Peresani et al. 2011) in Europe, as well as controversial sites such as Pedra Furada in Brazil (Santos et al. 2003).

Early agricultural and pastoral societies settled in karstic landscapes in regions as different as the Mediterranean and subtropical China. Within the semiarid strongly seasonal Mediterranean climate, karstic wetlands seem to have acted as major attractors for foraging and farming communities alike through glacial and interglacial cycles (Balbo 2009). Some of the major present-day European pastoral communities are still found in karstic landscapes in the Alps, the Pyrenees, and the Dinarides (Angelucci et al. 2009). On the other side of the world, in a completely different climatic setting, the humid steamy to subtropical conditions that characterize the South China karst have contributed to the formation of spectacular landscape features such as stone pinnacle forests, cone and tower karsts, huge sinkholes, natural bridges, and caves. It is within these settings that some of the earliest evidence of rice agriculture in Asia has been discovered within the framework of "The Early Rice Agriculture and Pottery Production Project."

Megalithism, Urban Contexts, and Early Civilizations

A significant portion of European megalithic archaeology is found in karstic landscapes. Stonehenge is but one of the best-known examples. Less-known examples, also from the British Isles, include the Burren uplands, a karstic landscape located on the midwestern coast of Ireland, and the karstic landscapes of Western Britain. Other cases of early megalithism in karstic landscapes come from Mediterranean Islands (Corsica, Sardinia, Malta, Cyprus, the Balearic Islands to cite but a few) (e.g., Cassar 2010; Feeser and O'Connell 2010). Karstic landscapes have provided the raw material to some of the most impressive early urban civilizations, for architecture and statuary work in Egypt (e.g., the Saqqara step pyramid), Europe (e.g., the Acropolis in Athens, the Minoan palace in Knossos), and Central and South America (e.g., buildings parts and decorations in Teotihuacan and Tikal) (e.g., Haviland 1970).

Geoarchaeology of Karstic Landscapes

Geoarchaeological applications in karstic landscapes contribute to some of the questions in

archaeology and human paleontology discussed above. Introduced along with a whole new array of field and laboratory archaeological methods in the 1950s, geoarchaeology has been formally defined in the 1970s as one of the latest developments within the archaeological sciences and environmental archaeology (Renfrew 1976). Mediterranean karstic landscapes have been a kind of testing ground for the discipline, with some of the earliest examples of geoarchaeological applications (e.g., Haua Fteah in McBurney 1967) (Fig. 3).

The geoarchaeological tradition in Mediterranean karstic regions has been continuous ever since (Barker and Bintliff 1999). Geoarchaeological applications are by definition multiscalar, based on methods spanning from spaceborne observations through remote sensing for physiographical characterization and archaeological site detection (e.g., Lasaponara and Masini 2011) to the sedimentological study of alluvial and colluvial sequences and cave fills for paleoenvironmental reconstructions (e.g., Brown 1997; Woodward and Goldberg 2001; Balbo et al. 2006; Iriarte et al. 2011; Marriner et al. 2012), site preservation assessment and formation processes of stratified archaeological deposits (e.g., Angelucci 2003; Araujo et al. 2008; Mallol et al. 2009; Iriarte et al. 2010), and the micromorphology of specific anthropic features (e.g., Wadley et al. 2011) as well as paleosoils and ancient field systems (e.g., Fuchs and Lang 2004; Sedov et al. 2008; Puy and Balbo 2013). More recently, coastal and submerged archaeology in karstic regions is opening new horizons for the application of geoarchaeology underwater, e.g., in the context of Central American and Caribbean archaeology (e.g., Faught and Donoghue 1997; Beeker et al. 2002).

Geoarchaeology of Subterranean Karst

Among the different geoarchaeological specialties, micromorphology has been widely applied in karstic caves (Goldberg and Berna 2010). Beside the assessment of site formation and taphonomical processes (Angelucci 2003; Araujo et al. 2008; Mallol et al. 2009; Iriarte et al. 2010), micromorphology (Stoops 2010) and microarchaeology (Weiner 2010) have been used to put under scrutiny some of the earliest evidence for the use of fire at Zhoukoudian cave 1 Ma (Weiner et al. 1998). On the other hand, based on the same methods, Berna et al. (2012) recently demonstrated cooking capabilities among hominins 1.2 Ma at Wonderwerk Cave, Northern Cape province, South Africa. On a similar note,

Karstic Landscapes: Geoarchaeology, Fig. 3 Resuming excavations at the Haua Fteah karstic cave in 2007 half a century after Charles McBurney made here some of the first systematic applications of geoarchaeology in the 1950s

microscopic techniques have been used in the karstic cave of Klisoura (Greece) to identify the earliest example of clay hearths 34 to 23 ka (Karkanas et al. 2004). One of the best-understood features in cave micromorphology in connection with animal domestication and husbandry is that of spherulites, carbonatic nodules found in ovicaprid dung that is found in great quantities in caves that have served for animal keeping (Canti 1997). Shahack-Gross (2011) has recently proposed an overview of microscopic features related to animal husbandry that find application in most Holocene anthropic karstic cave deposits.

Karstic rock-shelters and caves also provide archives of past environmental change that can be analyzed using methods integrated in the geoarchaeological approach (Woodward and Goldberg 2001). The isotopic study of speleothems provides key information on past environmental and climatic change (McDermott 2004). In Sicily, speleothems have provided highly resolved continental records of Holocene climate in connection with the spread of agriculture (Frisia et al. 2006). Frumkin et al. (2009) provide an example of how geochronology (Walker 2006) and isotopic analysis of speleothems were used to reconstruct long-term cave stratigraphy within the Qesem karst system in Israel.

Geoarchaeology of Surface Karst

Geoarchaeology allows the combination of physiographical characterization (through remote sensing and geomorphology) and archaeological survey in surface karstic landscapes. This hybrid approach is necessary to fully understand the significance of the archaeological and paleontological record preserved in caves within its broader environmental and socio-ecological context. Gaps in the often ill-preserved surface archaeological record can then be critically read in function of the preservation biases involved. Within karstic regions, this approach has revealed large numbers of open-air archaeological sites from the Pleistocene and Holocene periods (e.g., Runnels et al. 2004; Andel and Runnels 2005; Balbo 2009). In some instances and in spite of the generally poor taphonomical conditions, exceptional preservation has been maintained within archaeological sites found in surface karst landscapes. The Lower Paleolithic site of West Stow, found in a depression within the chalk karst region of West Anglia, provided evidence of the use of fire in Europe as early as 450 ka (Barendregt et al. 2005; Preece et al. 2006). Micromorphology and isotopic studies have been used in the region to reconstruct past climatic settings (Candy 2009).

A recent review by Coxon (2011) provides an insight into issues concerning the impact of agriculture on karst terrains and their management. Geoarchaeology has provided support to research on early agricultural adaptations and impact within the main foci of plant and animal domestication (e.g., the Levant) as well as in peripheral areas (Thomas 1990; Homburg and Sandor 2011). Using ground-penetrating radar (GPR), Munro-Stasiuk and Manahan (2010) and Gunn et al. (1995) studied ancient Maya field systems in the karst terrains of Northern Yucatan, Mexico. Geoarchaeological methods (mostly coring and geophysics) are among the main tools deployed in the "Early Rice Agriculture and Pottery Production Project" to study early rice agriculture in tropical karstic China. Apart from the definition of irrigation and terrace field systems, the geoarchaeological approach to the study of agricultural systems in karstic landscapes involves the reconstruction of the environmental settings prior to the introduction of the new agricultural order through the analysis of the underlying paleosols and nearby sedimentary sequences. Examples are found across the Holocene, from Neolithic agricultural soils in the Levant (Iriarte et al. 2011) to the complex irrigated terrace systems of Medieval Al-Andalus (Puy and Balbo 2013) and SE Asia, where clusters of terrace fields such as those of Ifugao (Philippines) have been inscribed in 2001 in the UNESCO list of world heritage in danger.

Within open karstic landscapes, karst depressions are perhaps the best archives for geoarchaeologists to find past environmental proxies preserved and propose reconstructions of human-environment interaction (Siart et al. 2010). Karstic wetlands function as refugia and transitional (buffer) zones and have acted as attractors for mobile hunter-fisher-gatherers, herders, and

settled agriculturalists (Coles 1984; Gams et al. 1993; Nicholas 1998).

In some instances karstic wetlands have given geoarchaeologists exhaustive continental paleoenvironmental sequences (e.g., Giraudi 2001; Lawson et al. 2004; Balbo et al. 2006), more complete and less biased by human action than those usually found in cave contexts. Likewise, wetlands have provided some of the best contexts for the application of geoarchaeology in waterlogged conditions within karstic regions. It is within the mixed karstic and volcanic landscape of the shore of the Sea of Galilee (Israel), the lowest freshwater lake of the world, that perfectly preserved remains of bedding were studied microscopically within the 23 ka fisher-hunter-gatherer camp of Ohalo II (212–213 m below mean sea level) in occasion of a rapid drop of the water level in the lake (Nadel et al. 2004). Velušćek (2004) provides an overview of lake-dwelling sites found in the karstic region of Slovenia. Another example, currently under investigation, is the Neolithic lake dwelling of La Draga (Spain), where micromorphology is employed in a multidisciplinary approach to clarify site formation and taphonomical processes and lakeshore sediment and pedological analyses are used to reconstruct past environmental change (Palomo et al. 2011).

Early Civilizations, Geohazards, and Submerged Geoarchaeology

Megaliths have been the focus of much archaeological research. Focus has been put on their value as ritual and astronomical centers for early agricultural societies. More recently, the involvement of geoarchaeologists in the study of their immediate environment has revealed salient aspects of the surrounding landscape, indispensable for a full understanding of these early building complexes (Pearson et al. 2008).

Geoarchaeology is becoming more and more integrated in the study of early civilizations, some of which are located in regions predominated by karstic landforms, as discussed above. Geoarchaeological applications within and around archaeological contexts in the tropical karst of Yukatán have focused on the impact Maya had on the local environment, their use of space within settlements, and their use of cenotes as sources of freshwater (Gilli et al. 2009; Hutson et al. 2009). In Egypt, sedimentology and geomorphology have been used to define paleoenvironmental and landscape dynamics (Ghilardi and Tristant 2012 and references therein). Within ancient urban contexts located in tectonically active karstic regions, geoarchaeology has been used to detect and date past geohazards, e.g., along the Dead Sea fault where earthquakes had devastating effects on the Late Byzantine communities of Syria (Marco 2008). The occurrence, impact, and media coverage of recent geohazards have inspired ever more geoarchaeologists to study the effects of such events as earthquakes, volcanic eruptions, and tsunamis (many of which happen to affect karstic regions) on past societies using sedimentology, micropaleontology, archaeology, and geochemistry (e.g., Reinhardt et al. 2006; Goodman-Tchernov et al. 2009). On a similar note, geoarchaeology has found significant applications in the understanding of the dynamics of site abandonment of karstic coastal areas due to submersion following sea-level rise in the Holocene (e.g., Florida in Faught and Donoghue 1997). Some of the karstic caves submerged following sea-level rise in the Pleistocene-Holocene transition have given remarkable rock art as well as important paleoenvironmental information, e.g., the Cosquer cave off the shore of Marseille (France) (Collina-Girard 2004).

K

International Perspectives

The international presence and visibility of the geoarchaeology of karst landscapes in conferences and research institutes is briefly discussed in view of a possible more consistent future definition.

The Geoarchaeology of Karstic Landscapes at International Conferences

In general, geoarchaeology is gaining weight at international conferences on geosciences and archaeology. European Geosciences Union (EGU) Assembly in April 2011 had a full session dedicated to “Late Quaternary environments and

societies: progress in geoarchaeology." At the International Quaternary Association (INQUA) congress in July 2011, "Geoarchaeology: palaeoenvironments and human interaction" was the most extended session. Similarly, international conferences on archaeology have also seen a steep rise in geoarchaeological contributions in recent years. The Society for American Archaeology (SAA) conference in April 2012 dedicated a general session to "Geoarchaeology and Geophysics." In contrast, the European Archaeological Association (EAA) conference in August–September 2012 had no specific session dedicated to geoarchaeology.

Although several geoarchaeological case studies presented at international geosciences and archaeology conferences have been developed in karstic landscapes, a fully dedicated session has not yet been organized. Likewise, at specialist conferences and sessions dedicated to karstic landscapes, geoarchaeology plays only a little part, e.g., at the International Association of Sedimentologists (IAS) meeting in September 2012, where a full session on "Karst, cave sediments and speleothems" was devoted to karst formation, cave deposits, geochemistry, chronology, and climatic reconstruction. Similarly, although focusing on geoarchaeological applications in karst-dominated Mediterranean landscapes, the International Colloquium on Geoarchaeology in September 2011 did not have a session fully dedicated to geoarchaeological applications in karstic landscapes.

Dedicated Institutes and Research Clusters

Institutes dedicated to karst landscapes exist worldwide (Veni 2011). However, few of them explicitly include geoarchaeological research among their activities. Existing research clusters and institutions dedicated to karst landscapes are located in the hearth of emblematic karstic regions. The Department of Geography, Environment and Planning at the University of South Florida has a research cluster on "Karst and wetland environments," including a specific research line on the geoarchaeology of karst landscapes in Belize, Israel, Poland, and Spain. The Centro de Estudos em Geografia e Ordenamento do Território (CEGOT), Faculdade de Letras, Universidade de Coimbra (Portugal), includes a "Karst research group" focusing on cave deposits, paleoclimatic reconstructions, and cave and rock-shelter geoarchaeology in Portugal, Italy, and France. Outstanding international initiatives include the "Interdisciplinary Studies of Karstic Landscapes (INTERKRAS)," an EU-funded project within the "Long Life Learning Program (ERASMUS-IP)." INTERKRAS includes geoarchaeology among its approaches to training students to the integrated long-term study of karstic landscapes, viewed as a combination of natural and cultural heritage.

Future Directions

Major questions in archaeology and human paleontology involve the study of deposits found within karstic regions. The integration of methods from archaeology and the geosciences in geoarchaeology provides the tools for a multi-scalar approach to such issues as the construction of the domestic environment (e.g., control of fire, construction of floors, and beddings) and the transformation of the surrounding environment (e.g., construction of field and irrigation systems). Micromorphology and geomorphology provide an insight into formation and taphonomical processes. Sedimentology and pedology allows proposing paleoenvironmental, climatic, and land-use reconstructions.

In spite of recent attempts at drafting a synthesis of new directions in karst geoarchaeology (e.g., Reeder 2011), a comprehensive overview including karstic landscapes as a whole, i.e., subterranean and superficial karst systems, is still missing. Historically, the main focus of karstic geoarchaeology has been on caves and shelters. However, it is within exokarstic depositional environments that geoarchaeology is likely to bring a greater contribution to karstic landscape archaeology in the coming years. It is within superficial and submerged karstic deposits that most univocal evidence of human activity in karstic landscapes is likely to emerge in the near future, from poljes, dolines, incised river valleys,

to submerged coastlines. Geoarchaeology provides the necessary framework to maximize information found in these environments.

An increasing number of centers interested in archaeology and socio-ecological systems are applying geoarchaeological approaches in karstic landscapes. Although research tools are ever more refined, the promotion of a coherent teaching framework is still lacking. Innovative future teaching resources will benefit from an exhaustive review and systematization of information scattered online, in print, and in class. The outcome of such review could span from specific textbooks to conference sessions as well as university and online courses on the geoarchaeology of karstic landscapes. An international commission of experts focusing on the geoarchaeology of karstic landscapes, possibly clustering as a web community stemming from the present initiative, would bring great benefit to the definition of a discipline apt to solving major issues in archaeology.

Kaulicke, Peter

Rafael Vega-Centeno
Pontificia Universidad Católica del Perú, Lima, Peru

Basic Biographical Information

Peter Kaulicke is a German archaeologist who has dedicated his entire career to the study of Andean pre-Hispanic populations and cultures. He was born in Buntenbock, near Hannover in 1946, and studied at the University of Bonn receiving his degree of Doctor of Philosophy in American Studies in 1980. Prior to completing his doctorate, he traveled to Peru in 1971 to begin his long-term research in and commitment to Andean archaeology. He first participated in field research projects organized by the *Instituto Riva-Agüero* of the Pontifical Catholic University of Peru (PUCP) in Lima. Subsequently, he joined research projects conducted by the Andean Rural History Seminar and the School of Archaeology of the National University of San Marcos. Under the auspices of these institutions, Dr. Kaulicke conducted excavations at the Uchkumachay Cave in Peruvian central highlands and at the site of Pandanche, a medium-sized platform mound located in the northern highlands.

After getting his degree, Dr. Kaulicke returned to Peru and founded in 1982 the Archaeology Program at the PUCP, where he later has become full-time professor, and dedicated himself to fostering this program and its students as well as pursuing his research interests.

Between 1987 and 1991, Dr. Kaulicke conducted research in the Piura Valley in the Peruvian northern coastal desert, studying the Mochica occupation of that region through excavations at Huaca Nima, Loma Macanche, and Loma Valverde sites. More recently, since 2011, he has conducted research in the Rio Grande Valley in the Peruvian south coast, addressing the characteristics of Paracas culture occupations of that region.

Dr. Kaulicke has also been the editor of the first 12 volumes of the *PUCP Archaeology Bulletin* and organized during a span of 10 years a series of international symposia on major themes and issues of significance to Andean archaeology at this university.

Major Accomplishments

Dr. Kaulicke's contribution to Andean archaeology can be addressed in three areas. First, as a researcher, his work became particularly important in clarifying chronological issues on Andean archaeology. Kaulicke contributed to establish cultural sequences of early hunter-gatherers (1981), early formative occupations (1975), and latter complex societies (2006). His long-standing concerns on chronology have resulted in comprehensive studies on the chronology of the Peruvian Formative Period (1994, 2010).

Dr. Kaulicke has also dedicated his studies to understand the relationships among ancestorship, burial practices, and Andean symbolic universes. His remarkable studies on death and memory

(2000) and water systems and ancestorship (2005) illustrate this line of research. Furthermore, he produced the most comprehensive analysis of the iconography of the famous Cerro Sechín site, offering a solid and refreshing interpretation on the meaning of more than 50 stone-carved images that decorate the exterior walls of the Cerro Sechín temple (1996).

The contributions of Dr. Kaulicke also include the reediting and diffusion of pioneers of Peruvian archaeology, particularly the work of Max Uhle, who conducted the first scientific research in Peru at the end of the nineteenth century. Kaulicke has been responsible for the translation and republishing of the important but poorly known contributions of German authors like Max Uhle but also of Hernan Trimborn, Jacobo von Tshudi, and Anke Wendt. A whole generation of Peruvian archaeologists has become benefited by this effort.

Finally, Dr. Kaulicke has been a leading figure in the growth of Peruvian scholarship, conducting for 10 years international symposia that brought to Lima the most prominent foreign and Peruvian archaeologists, historians, and anthropologists, to discuss recent finds and interpretations of nearly all the epochs of pre-Hispanic history. Edited proceedings of these symposia resulted in the first 12 volumes of the *PUCP Archaeology Bulletin* (*Boletín de Arqueología PUCP*) that, since then, has become a major reference on Andean archaeology.

Keatley Creek and Bridge River: Complex Hunter-Gatherer Villages of the Middle Fraser Canyon

Anna Marie Prentiss
Department of Anthropology, The University of Montana, Missoula, MT, USA

Introduction

Complex hunter-gatherers depart from the traditional model of hunter-gatherers as small relatively egalitarian groups, engaged in frequent residential moves, employing little formal storage and consuming a very broad diet drawn from non-domesticated food sources (Lee 1968). In contrast, complex hunter-gatherers often live in large groups, are typically characterized by social status distinctions, move residences somewhat infrequently, rely upon storage, and typically specialize in select non-domesticated food sources (Sassaman 2004). Archaeologists have been interested in better understanding variation in the evolution and organization of these societies. The archaeological record of complex hunter-gatherers is widespread and includes such archaeological entities as the Middle Jomon culture of Japan, the northern European Mesolithic, the Natufian of the Near East, the Thule Eskimo

Keatley Creek and Bridge River: Complex Hunter-Gatherer Villages of the Middle Fraser Canyon, Fig. 1 Map of Middle Fraser Canyon showing approximate locations of Bridge River and Keatley Creek sites. (Map created by Guy Cross)

tradition of North America's Western Arctic, the Marpole phase of British Columbia's southern coast, and the Lillooet Phenomenon of Interior of British Columbia. The Lillooet Phenomenon is best represented by two important archaeological sites known as Keatley Creek and Bridge River (Fig. 1). These sites have become particularly important for their fine-grained data reflecting development of socioeconomic and political complexity in this region of North America (Prentiss and Kuijt 2012).

Definition

The Keatley Creek and Bridge River sites are housepit villages (Figs. 2 and 3) located in the vicinity of Lillooet, British Columbia, and densely occupied during the period of approximately 1,800 to 200 years ago (Prentiss and Kuijt 2012). Housepits are semi-subterranean dwellings with large wooden superstructures and earthen caps. Entrances to the dwellings could be on the side, or in larger structures, down a ladder made from a hollowed tree trunk, through a hole in the roof. Normally, one or more extended families resided in the houses, and the largest structures could hold 50 or more people. Keatley Creek and Bridge River are particularly large villages, containing, respectively, 115 and 80 housepits. At peak size each site may have been occupied by groups in excess of 600–800 persons (Hayden 1997; Prentiss et al. 2008).

Archaeological research at the Keatley Creek and Bridge River sites began during the late 1960s with Arnoud Stryd's Lillooet Archaeological Project. Stryd visited Keatley Creek and conducted limited test excavations at Bridge River. His primary focus, however, was a somewhat smaller village known as the Bell site. Excavations at Keatley Creek began in 1986 under direction of Brian Hayden, whose research at the site continues to the current period (Hayden 1997). Anna Prentiss excavated at Keatley Creek in 1999–2002 (Prentiss et al. 2007). She then conducted mapping, geophysical studies, and excavations at Bridge River from 2003 through 2012 (Prentiss et al. 2008, 2012).

Archaeological investigations at Keatley Creek and Bridge River have had a number of significant outcomes. All archaeological interpretations in the Middle Fraser Canyon have been enhanced by an excellent ethnographic and ethnoarchaeological record (Hayden 1992). Indeed, partnerships between archaeologists and indigenous groups have led to a range of creative studies and interesting conclusions about the recent and more remote past (Prentiss and Kuijt 2012).

The housepits of Keatley Creek and Bridge River have outstanding stratigraphic records and preservation of organic materials including wood and basketry in some contexts. It has been possible to chronicle many details of the life histories of particular households. The Bridge River site has proven particularly productive as many housepits feature stratified sequences of buried floors. Housepit 54, for example, included a sequence

Keatley Creek and Bridge River: Complex Hunter-Gatherer Villages of the Middle Fraser Canyon,
Fig. 2 Photograph of Keatley Creek site showing core area with greatest density of housepits

Keatley Creek and Bridge River: Complex Hunter-Gatherer Villages of the Middle Fraser Canyon,
Fig. 3 Photograph of Bridge River site showing a portion of the core area with highest density of housepits

of 13 distinct clay floors and seven roof deposits. These contexts provide the rare opportunity to examine household histories (Ames 2006) that sometimes span hundreds of years at a level of resolution rarely available to archaeologists working with complex hunter-gatherers (Prentiss et al. 2012).

The combination of fine stratigraphy, excellent preservation of materials, frequent house features, and abundant artifacts has permitted archaeologists to conduct fine-grained analysis of the evolution and organization of the complex societies that resided at these places. Brian Hayden's (1997) research emphasized intra- and inter-household variation in artifacts, food remains, and storage features as indicators of inter-household ranking at Keatley Creek. He sought to demonstrate that largest houses were able to accumulate more nonlocal goods such as shell jewelry and jade and soapstone tools, along with large quantities of high-quality food such as Chinook salmon. This permitted him to argue that during the time of peak occupation, social life was organized around a system of elite-dominated

manipulation of debt capital, manifested in elaborate feasts and potlatches similar to those of the nearby Northwest Coast groups. Prentiss and colleagues (Prentiss et al. 2012; Prentiss and Kuijt 2012) recognized markers of similar behavior at the Bridge River site as manifested in part by evidence for feasts featuring young dogs, salmon, and deer, along with differential accumulation of prestige goods such as copper jewelry and jade tools.

A final significant contribution of archaeological research in the Middle Fraser Canyon has been the recognition of a range of ritual behavior in housepits. Evidence for feasting is known from Keatley Creek and Bridge River. However, recent studies by Hayden and colleagues (Hayden and Adams 2004) have also revealed small houses on the periphery of the Keatley Creek village with evidence for a variety of ritual activities including the possible activities for special social groups and shamans. Research at these places is ongoing, and it remains to be seen whether they are related to the larger occupations in the core village. Regardless, they provide a window into an aspect of behavior among hunter-gatherers rarely available to most archaeologists.

Key Issues/Current Debates/Future Directions/Examples

There are several issues debated in Middle Fraser Canyon archaeology centered on chronology, socioeconomic change, political evolution, and village abandonment. Archaeologists differ over the founding of the large Middle Fraser villages (Prentiss and Kuijt 2012). Brian Hayden has argued for early dates in excess of 2,600 years ago, while Prentiss, drawing from more recent excavations and radiocarbon dating, argues for a start date of less than 1,800 years ago. Archaeologists also differ on interpretations of socioeconomic and political history. In brief, Brian Hayden (1997) contends that once present, the villages changed little in basic economy and political organization. In contrast, Prentiss and colleagues (Prentiss and Kuijt 2012) have presented new data suggesting that the Keatley Creek and Bridge River villages grew as much as 300% between 1,800 and 1,200 years ago. During that time, subsistence economies remained dominated by salmon, but the role of mammals gradually increased in importance, particularly after 1,200 years ago when salmon fishing apparently became less productive. Prentiss also argues that it was under the latter period that social status differences became obvious in the villages. Thus, drawing from Bridge River and Keatley Creek data and in contrast to Hayden, Prentiss contends that material wealth-based inequality was not obviously present in the early history of the villages. A final source of debate concerns the abandonment of the villages at around 1,000 years ago (Prentiss and Kuijt 2012). Brian Hayden and colleague June Ryder argue for an abrupt abandonment due to a massive landslide. This argument has been critiqued by Ian Kuijt who points out that there is no firmly dated evidence for such landslides. Prentiss and Kuijt (2012) contend that dense human populations and local depression in terrestrial food resources could be a more likely cause.

Future archaeological research in the Middle Fraser Canyon will seek to test alternative hypotheses offered by Hayden and Prentiss. In addition, archaeologists should explore a number of other critical issues. How were the Keatley Creek and Bridge River villages organized sociopolitically during their earliest occupations? How and why did life in these villages change over the following centuries? In particular, what were the conditions that favored the rise of archaeologically obvious socioeconomic and political competition? What was the role of this socially competitive process in the demographic decline and abandonment of the villages? Application of new research approaches will be essential to advancing knowledge of the ancient cultures of the Middle Fraser Canyon. Geophysical remote sensing techniques have been very productive for mapping subsurface features (Prentiss et al. 2008). Studies of paleo-DNA have been initiated and have shown promise, particularly in the identification of salmon species and recognition of domesticated dog

lineages. Finally, researchers will need to develop more advanced studies of organic residues on tools and in floor sediments in order to resolve questions regarding the roles of many plant foods, particularly geophytes (plants with edible roots).

Keel, Bennie C.

Michele C. Aubry
Alexandria, VA, USA

Basic Biographical Information

Bennie Carleton Keel is an American archaeologist and government official. He grew up in Panama City, in Florida and graduated from Bay County High School in 1952. He completed 1 year of college before enlisting in the US Army (1954–1957) and serving as a military policeman with the 11th Airborne Division at Fort Campbell, Kentucky. After military service, he completed undergraduate studies in anthropology and sociology at Florida State University where he received B.S. (1960) and M.S. (1965) degrees. He undertook graduate studies in anthropology and quaternary studies at Washington State University in Pullman where he received a Ph.D. (1972).

Early in his career, Bennie Keel worked on several government-sponsored archaeological projects including the Weiss Reservoir in Alabama, the Town Creek Indian Mound in North Carolina, and the Marmes Rockshelter in Washington. He was the archaeologist at the Research Laboratories of Anthropology at the University of North Carolina in Chapel Hill (1964–1967; 1969–1973), taught at St. Andrews Presbyterian College (1971) and Wright State

University (1973–1976), and worked on compliance projects in Ohio.

In 1976, Dr. Keel was hired by the National Park Service (NPS) to lead its Interagency Archeological Services Division in Atlanta, Georgia. In 1980, he was promoted to head the division's headquarters in Washington, DC, and serve as the Department of the Interior's Departmental Consulting Archeologist. In 1983, he was promoted to serve as Assistant Director for Archeology and continued as Departmental Consulting Archeologist. In 1990, he transferred to the NPS Southeast Archeological Center in Tallahassee, Florida, serving as Regional Archeologist (1990–2007) and Director (2007–2008) until his retirement.

Major Accomplishments

Bennie Keel's career in archaeology, spanning five decades, was coterminous with a period of significant change in American archaeology. During this time, many federal laws were passed, and presidential executive orders were issued calling on federal, state, and local governments and Indian tribes to preserve and protect the nation's archaeological resources. It was a time when the federal government was establishing its approach to managing these important resources. Bennie Keel was in a unique position to do groundbreaking work, and he had a profound influence on the direction the government took. He played a key role helping establish the framework for the federal archaeology program that exists today.

Dr. Keel brought a fresh approach to contract management in the southeastern United States in the 1970s. Most importantly, he instituted transparency in archaeological contracting. He insisted that contracts not only were academically justifiable, they also were fiscally responsible and in the public interest. He promoted the concept of treating large-scale federal undertakings as single archaeological districts to optimize and rationalize decision-making and insisted that major projects produce popular publications.

Dr. Keel oversaw development of regulations and guidelines of major impact nationally in the 1980s. The *Protection of Archaeological Resources: Uniform Regulations* (18 CFR 1312, 32 CFR 229, 36 CFR 296, 43 CFR 7) help federal land managers preserve and protect resources under their jurisdiction or control. The *Curation of Federally-Owned and Administered Archeological Collections* regulation (36 CFR 79) helps agencies care for their collections. The *Abandoned Shipwreck Act Guidelines* help government owners comprehensively manage shipwrecks. Dr. Keel also promoted development of the National Archeological Database and the NPS Cultural Sites Inventory, reported to Congress on federal archaeology (Keel et al. 1989), highlighted federal program accomplishments (Keel 1988), and encouraged peer review (Keel et al. 2007), archaeological resource protection (Keel 1991) and cultural conservation (Loomis 1983).

Dr. Keel developed a long-range plan (Keel et al. 1996) to help 64 southeastern NPS units identify their archaeological resources. He directed or coordinated projects at Cane River Creole National Historical Park (Keel 1999), Charles Pinckney National Historic Site, Fort Raleigh National Historic Site, Great Smoky Mountains National Park, and Timucuan Ecological and Historic Preserve. The Ravensford land exchange work (Keel 2007) at Great Smoky Mountains was the largest single Cherokee archaeology research project in North Carolina and set new standards for fieldwork.

Dr. Keel has received numerous awards for his contributions to the profession including the Department of the Interior Superior Service Award (1979), the Society of Professional Archeologists Distinguished Achievement Award (1993), the Southeastern Archaeological Conference Lifetime Achievement Award (2008), and the Society for American Archaeology's Lifetime Achievement Award (2012). A symposium recognizing his contributions to the development of North Carolina archaeology was held in 2008 (Davis 2010).

Early in his career, Bennie Keel gained renown for his pioneering research into Cherokee origins, and his book *Cherokee Archeology: A Study of the Appalachian Summit* (1976) remains the most

comprehensive analysis of late prehistoric archaeology in this area.

Kennewick Man Case: Tribal Consultation, Scientific Studies, and Legal Issues

Francis P. McManamon
Center for Digital Antiquity, School of Human Evolution and Social Change and ASU Libraries, Arizona State University, Tempe, AZ, USA

Introduction

The human skeletal remains now referred to as the "Kennewick Man" or the "Ancient One" were found in July 1996 in shallow water along the southern shore of Lake Wallula, a section of the Columbia River pooled behind McNary Dam in Kennewick, Washington. In February 2017, at an undisclosed location somewhere in the internal basin of the Columbia River, not far from the river, the remains were reburied by members of the tribes who had constantly sought such an outcome throughout the more than two decades since the discovery of the remains. This act concluded, if it did not resolve, arguments about how this set of ancient human remains should be treated. One can anticipate that cultural, legal, and scientific aspects of the case will continue to be debated and discussed in the future although the proximate question about how to treat the remains has been answered.

Discovery and the Start of the Case

The Kennewick skeletal remains were discovered by a pair of college students wading in the shallow water along the southern bank of Lake Wallula. From the end of July 1996, when the remains were first recognized until early September, whole and fragmentary human skeletal materials that eventually proved to be a single, nearly complete, and ancient human skeleton were gathered in shallow water from the bottom of Lake Wallula in Kennewick, Washington. The collection was made by James Chatters, a local professional archaeologist working for the county coroner. He recorded some

information about the remains and showed the remains to a few other individuals who inspected them briefly (Downey 2000:3–12; Nickens 1996, 1998). Based on these cursory inspections, many simple facts were unclear. For example, were these the remains of one or more than one individual, and what was the age of the remains? Were these the remains of a Euro-American settler or a "Native American"? If the latter, because they were found on land administered by the US Corps of Engineers (CoE), a federal agency, the Native American Graves Protection and Repatriation Act (NAGPRA) would apply to determine how the remains were treated. Radiocarbon testing of a piece of bone from the skeletal remains returned a very early date of about 8400 BP. When the date and other preliminary interpretations were announced at a press conference in August, the controversy regarding how the Kennewick remains should be treated became more pronounced and more widely known.

Over 350 separate, unarticulated human bones were gathered during several weeks by repeatedly wading in the water and picking up bones observed on the river bottom. We now know that the remains eroded into the lake from the river bank near the area where they were found. These remains were recovered from an extremely disturbed context; bones were collected, piece-by-piece, from beneath the shallow lake water with only general recording of their locations and spatial relationships (Nickens 1996, 1998; Chatters 2000: Fig. 3). The archaeological context, typically so informative concerning behavioral, chronological, and cultural interpretations, was lost almost completely after the remains eroded into the river bed. The skeletal remains were handed over to the CoE in early September 1996. Apart from brief notes made available in the fall of 1996, no further reporting about the initial collection activities and spatial distribution of the Kennewick remains at the discovery site was provided until 2000 (Chatters 2000). The CoE did not allow further study of the skeletal remains from that time until the government team studies that began in February 1999.

Despite the scanty information that was available at the time, individuals and organizations took steps to try and resolve the controversy that quickly developed concerning the proper treatment of the remains. Claims for repatriation were made by Indian tribes whose historical traditional territories overlapped the discovery site. Members of the scientific community called for full scientific study of the remains. In late September, local CoE officials began procedures to turn over the remains to the local tribes who claimed them. This attempt was challenged in federal court in October. In order to have time to address the legal complaint against the CoE, the court ordered the agency to halt its planned repatriation.

Reviewing the CoE activities during this period, the federal magistrate ruling on the case, John Jelderks, determined that the agency had not used adequate information to resolve the matter. In June 1997, he ordered the CoE to reconsider its decision-making and report to the court quarterly on its progress in resolving the matter.

Consultation with the Tribes and the Government Studies

At this point, the CoE and Department of the Army (DoA) turned to the Department of the Interior (DoI), which had expertise in both archaeology and the implementation of NAGPRA, for assistance. A series of discussions ensued involving officials from these departments and the Department of Justice (DoJ), which was representing the CoE in the case. In March 1998, the Secretary of the Interior agreed to assist the Secretary of the Army in resolving the issues related to the Kennewick Man human remains (Spiegel and Barry 1998). The Secretary agreed to have experts at the DoI assist in the case by:

1. Determining if the human remains found in the Columbia River near Kennewick, Washington, are "Native American" within the meaning of NAGPRA
2. Determining their appropriate disposition under the terms of the statute and its implementing regulations if these remains are found to be "Native American"

Within the DoI, the Departmental Consulting Archeologist (DCA) and National Park Service (NPS) were assigned to develop and carry out a program to resolve the issues at hand. Although one of the questions raised by the court was whether or not NAGPRA applied in this case, the NPS also undertook from its earliest involvement consultation with the Indian tribes that had come forward to claim the remains when they were found.

Most commentators and reporters described the legal controversy that developed and swirled around the Kennewick remains in rather superheated rhetoric pitting the interests of "science" against those of Native Americans. This characterization ignores the detailed, intensive, and wide-ranging historical and scientific investigation of the Kennewick remains undertaken by scientists and scholars as part of the government team's effort to determine the facts relevant to the questions in the case. Many news reports inaccurately suggested that scientific study of the Kennewick remains did not occur or that studies were hidden from the American public. In fact, this is quite untrue. A number of studies were conducted (McManamon 2013). These studies have been easily and publically accessible since shortly after their completion between 1998 and 2000, initially in a website maintained by the NPS Archeology Program, at (http://www.nps.gov/archeology/kennewick/). These reports and additional documents now also are available in tDAR (the Digital Archaeological Record) at (https://core.tdar.org/project/6325/the-archaeology-of-kennewick-man).

The government team responsible for trying to resolve the case successfully also organized and carried out a series of consultation meetings with representatives of the Indian tribes. These meetings, outlined in Table 1, were attempts to find common ground between the need to study the remains and the general opinion of tribal representatives that no studies were needed. The consultations also were justified on the grounds that if the Kennewick remains were found to be "Native American," consultation with possibly culturally affiliated Indian tribes would be required for compliance with NAGPRA. The combination of scientific studies and consultation with the tribal representatives reflects the balanced approach to resolving the case that characterized the overall approach of the government agencies involved.

As part of the consultation activities, the DCA, other DoI, NPS, and CoE representatives, as well as attorneys of the Department of Justice (DoJ), which was conducting the legal case, met with tribal representatives six times between 1998 and 2000 to ascertain the tribal perspectives on the case and to discuss the approach to the scientific studies, the rationale for such studies, and the results of the investigations (Table 1). The consultations all were held in the state of Washington at locations near where members of the tribes resided. The face-to-face meetings usually lasted for a day and gave officials of the agencies involved the opportunity to describe their plans

Kennewick Man Case: Tribal Consultation, Scientific Studies, and Legal Issues, Table 1 Consultations with claimant Indian tribes and scientific examinations

Date	Topic	Location
Consultation meetings with tribal representatives		
May 1998	Proposed approach for DOI investigation	Walla Walla
July 1998	Draft multiphase DOI investigation plan	Walla Walla
July 1999	Plans for bone sampling and C14 testing	Walla Walla
October 1999	Plans for cultural affiliation investigation	Walla Walla
February 2000	Plans for bone sampling for DNA testing	Walla Walla
July 2000	Cultural affiliation investigation/interpretations	Spokane
Scientific physical examinations and studies		
February 1999	Examination, documentation, measurement	Burke Museum, Seattle
September 1999	Bone extraction for C14 tests – two samples/split	Burke Museum, Seattle
April 2000	Taphonomy investigation; microsampling bone for aDNA analysis	Burke Museum, Seattle

to resolve various aspects of the case and listen to the concerns of the tribes. Officials considered many suggestions of the tribal representatives to fashion the necessary studies in ways that were as inoffensive as possible for the tribal members yet without compromising the methods and techniques essential for conducting the necessary historical and scientific research. Tribal representatives frequently expressed their frustrations with the process and the agencies' positions, but at least the meetings provided a channel for communication.

Consultation with tribes was a major part of the DoI's involvement. NAGPRA requires consultation with tribes that have or may have a cultural affiliation with the human remains of objects covered by the law. Section 3 "Consultation with the Tribes and the Government Studies" of the statute directs that consultations should start soon after any discovery of remains on federal land and should address issues related to excavation, documentation, analysis, recording, and ultimate deposition of the remains or objects in question. The Kennewick case presented a situation, not uncommon when remains that may be subject to NAGPRA are found accidentally, in which facts and evidence are needed in order to make determinations of whether the law applies and, if so, what disposition is appropriate. In such cases both scientific and historical investigations frequently are necessary to establish facts about the remains and answer basic questions. The studies necessary must be developed and conducted in concert with consultations with representatives of the tribes who were potentially culturally affiliated with the remains, although, except for discoveries on tribal lands, the consent of tribe(s) is not a requirement.

To resolve some of the factual matters in the Kennewick case and answer the interpretive questions asked by the federal court, the DCA organized and conducted three physical scientific examinations of the Kennewick remains (Table 1), as well as several background research investigations that did not involve direct examination of the Kennewick remains. The historical and scientific background research, undertaken between 1998 and 2000, included anthropology, archaeology, biology, history, linguistics, and traditional oral histories. Twenty-one nationally and internationally recognized scientists and scholars conducted this variety of historical and scientific examinations, analyses, tests, and studies (Table 2; McManamon 2013). Throughout this period and afterward the Kennewick skeletal remains were cared for professionally and skillfully by collection managers of the CoE Mandatory Center of Expertise for the Curation and Management of Archaeological Collections, curators at the University of Washington's Burke Museum, and additional conservation experts (Cassman and Odegaard 2004).

The detailed scientific examination and recording of the Kennewick skeleton, conducted at the Burke Museum, University of Washington, in late February 1999, were designed to be non-intrusive, that is, no physical samples of the remains were removed (Larson 1998; McManamon 1998; Smith 1998). The skeleton was physically examined, measured, and recorded using current and standard scientific methods and techniques. Sediments adhering to the bones and trapped within bone cavities were examined, described, and analyzed for similarity with the soil sediments in the vicinity of the discovery of the skeletal remains. The stone projectile point embedded in the skeleton's pelvis was described and analyzed.

The physical anthropological examination by Powell and Rose (McManamon et al. 1999, see chapter by Powell and Rose) indicates that the Kennewick skeleton represents a male who died between 45 and 50 years of age. He was about 5′ 9″ tall and well-muscled indicating a life of rigorous physical activity. His teeth have extremely worn surfaces but no caries. Evidence of arthritis is minor, and his joints were in excellent shape for a man of his age and activity. Early in his life, probably when he was still a teenager, he was involved in an accident or conflict in which a projectile point became embedded in the right iliac blade of his pelvis. His bones indicate that he recovered completely from this wound without any infection or disability and lived for many years afterward. Powell and Rose present many other details about the skeletal remains and their interpretation of them in their report.

Copies of reports of all of these investigations can be found in McManamon (2013) and accessed in tDAR (the Digital Archaeological Record)

[a]Individuals are listed with the professional affiliations they had when the investigations were conducted in 1999–2000. Dr. Phillip Walker is deceased

Like other ancient American skeletons, the Kennewick remains exhibit morphological features not found in modern populations. For all craniometric dimensions examined, Powell and Rose note that this is not unexpected given that the Kennewick remains date over 8000 years earlier than the modern samples used for most of the comparative analyses. The Kennewick cranial measurements are most similar to populations from the south Pacific, Polynesia, and the Ainu of northern Japan, a pattern observed for other crania with such very old dates from North and South America. This similarity does not mean that the Kennewick Man is an ancient Polynesian voyager who made his way up the Columbia River. Rather, the differences in cranial morphology observed probably reflect the complex events and different migrations of human populations into North America from 20,000 BP onward and the long ancient history of interaction among populations in the region since the original colonization of the continent (e.g., see Brace et al. 2001; Dillehay 2009; Schurr 2004).

Subsequent additional craniometrics analysis reported by Rasmussen et al. (2015, Supplemental Information No. 9) that was conducted along with the investigation of ancient DNA from the Kennewick Man skeleton concluded that the craniometrics features of the skeleton fall within the range of affinity patterns of individual Native Americans. Commenting on the 2015 craniometrics analysis, Meltzer (2015: 1489–1490 notes that "…early Native American crania seem to differ from those of modern Native

Americans. . .Craniometric variation is not solely a by-product of (separate) inheritance and history: mutation, isolation and drift, development and adaptation all converge to modify cranial form. . ..”

The February 1999 noninvasive examination included the removal, description, and analysis of soil sediments from the skeletal remains. Our original hope in using the sediments was that enough organic material from the original burial context of the remains could be obtained from the sediment adhering to the skeleton for a radiocarbon date to be made on it. However, during analysis it could not be determined with sufficient reliability that the sediments were not recently associated with the bones from the river or that they were not older sediments into which the Kennewick remains had been buried (McManamon et al. 1999, see Huckleberry and Stein chapter). Both possibilities created contextual problems that made radiocarbon dating of the sediment an unreliable proxy for the age of the skeletal remains.

The 1999 investigation of the Kennewick remains included a careful examination of the lithic object lodged in right pelvic bone. The object, which probably is a projectile point, was examined, documented, and analyzed in place. CT scans were essential to this part of the investigation. The descriptive information could not have been determined in any other nondestructive manner. They revealed that the object is at least 5.6 cm long and 2 cm wide at widest end, tapering to 3 mm wide at narrowest end. The object has two convex faces with a wide, rounded base and a narrow tapering tip. There is no evidence of notches or stem. The exposed portion of the object, around the middle, is 6–5.5 mm thick. Based upon comparative analysis with other specimens in collections at the Burke Museum and the Oregon State Museum, Fagan infers that the size, shape, and raw material give the object the appearance of a Cascade projectile point. However, these characteristics are not exclusive to Cascade points (McManamon et al. 1999, see Fagan chapter). The possibility that this object is a Cascade point is particularly interesting because archaeological site components containing such points are common throughout the Pacific Northwest. These site components often are associated with deposits of volcanic ash that originated during the eruption of Mt. Mazama approximately 7600 years ago.

The 1999 physical examination provided the basic description and detailed documentation of the remains that is required by the Archaeological Resources Protection Act (ARPA), NAGPRA, and other resource management and protection laws and regulations. The characteristics of the skeleton, the nature of the sediments embedded in and on the bones, and the attributes of the stone artifact in the pelvic bone all suggested an individual living a way of life consistent with an 8000-year date.

The information derived from the noninvasive studies, however, was not adequate to determine whether or not the remains fit the definition of “Native American” for purposes of NAGRPA, as understood by DoI officials at the time. Therefore, in order to make a reasonable decision about the age of the skeleton, which was considered at the time an essential aspect of making the “Native American” determination, DoI officials decided it was necessary to conduct additional tests, specifically radiocarbon dating of small samples of bone from the remains.

Following review and consideration of the results of the February examination, it was decided that two bone samples would be extracted from the Kennewick remains for radiocarbon dating. In September, bone samples were taken and sent to several radiocarbon dating labs to check and confirm the ancient date for the remains. Four C14 dates were obtained from these samples. The samples were processed and dated by Beta Analytical, Inc. (BA), of Miami, Florida; the Radiocarbon Laboratory of the University of California, Riverside (UC-R); and the NSF-Arizona AMS Facility of the University of Arizona. Two of the four new dates were in substantial conformance with the initial radiocarbon date of the portion of the metacarpal dated by UC-R in 1996. All the bone samples showed very low carbon content which slowed the processing of the samples and extended the time required to interpret the results. Taylor et al. (2001) describe this problem with

dating ancient bone samples and also note the variability of carbon preservation displayed by the Kennewick samples.

The BA date (Beta-133993) gave a conventional radiocarbon age of 8410 ± 40 BP. The equivalent calibrated radiocarbon age (using the two sigma, 95% probability) in years BP is cal BP 9510–9405 and cal BP 9345–9320. The bone sample used for this date was approximately half of the right metatarsal, one of the load-bearing bones of the foot. The UC-R lab processed and dated two of the Kennewick bone samples. Like the BA sample, both of these were very low in carbon content. Due to the low carbon content and the lack of clear collagen-like characteristics of the extracted carbon, the dates were reported as "the apparent C14 ages" for each sample. One of the samples was dated as 8130 ± 40 BP (UCR-3806/CAMS-60684), slightly different from the BA date but not inconsistent with it. These two samples, in fact, are from the same bone, the right first metatarsal. Both of these dates (Beta-133993 and UCR-3806/CAMS-60684) are consistent with the earlier C14 date (from the 1996 test) obtained from a portion of the fifth left metacarpal. The BA date, in fact, is almost identical to the first C14 date (McManamon 2000). The University of Arizona date (AA-34818) displayed very low carbon preservation, below the threshold for which the laboratory normally would report a date.

The C14 chronological information added to other information about the remains that supported the determination that the Kennewick skeletal remains should be considered "Native American" as defined by NAGPRA. All the dates obtained from the Kennewick Man samples predate 6000 BP and are clearly pre-Columbian. Two of the dates match closely the C14 date obtained in 1996 on another bone fragment believed to be from the skeleton. This chronological information, along with the results of the earlier documentation, examination, and analysis of the remains themselves, led the DoI to conclude that, for the purposes of NAGPRA, the Kennewick remains should be considered as "Native American," thus subject to the provisions and procedures of the law (McManamon 2000).

With this initial determination made, the government team next had to resolve the question of whether or not the Kennewick remains could be "culturally affiliated" with any of the Indian tribes who were claiming the skeleton as their ancestor. The DCA organized and coordinated the preparation of a series of scholarly reports by experts summarizing archaeological, biological, historical, linguistic, and traditional information that could be used for determining the cultural affiliation of the Kennewick remains (McManamon et al. 2000a). In April 2000, as part of the effort to determine the cultural affiliation of the Kennewick remains, an additional physical examination of the remains was conducted and samples taken to conduct tests for the detection of ancient DNA in the bones. Physical anthropologists Clark Larson, Joseph Powell, and Phillip Walker conducted macroscopic and microscopic examinations of the Kennewick skeleton to determine the suitability of specific skeletal elements for DNA analysis (McManamon et al. 2000b).

The 2000 taphonomic examination confirmed the conclusion of Powell and Rose, based on their 1999 examination that these are the remains of a single individual who was interred at the site, not one whose remains decomposed on the surface of the ground or who was incorporated into the deposit through a catastrophic flood event. This conclusion is supported by the completeness of the skeleton and the absence of any clear indications of carnivore scavenging of the remains.

During the April 2000 examination, microsamples were taken from the most suitable skeletal elements for analysis of the ancient DNA of the skeleton. The samples were analyzed by ancient DNA laboratories at the University of California – Davis, the University of Michigan, and Yale University. Each lab attempted to isolate and amplify ancient DNA from the skeleton; however, none of the tests were able to isolate and examine any ancient DNA (McManamon et al. 2000b).

In September 2000, Secretary of the Interior Bruce Babbitt recommended to the DoA Secretary Louis Caldera that the Kennewick remains could be culturally affiliated with the claimant tribes (Babbitt 2000). His decision was controversial within the DoI, where different interpretation

and procedure were advocated by some of the officials involved in the case. The decision was criticized in the wider world as well (e.g., The Economist 2000), although supported strongly by the American Indian community.

Subsequently, following a 2-year-long review by the district court, the DoI determination that the Kennewick remains were culturally affiliated with the claimant tribes was rejected in a decision released in August 2002 (Jelderks 2002). The judge commented that the scientific evidence presented by the DoI's investigations actually argued against the Secretary's determination and was not adequately taken into account in the reaching his conclusion. The district court also ruled that NAGPRA did not pertain to the Kennewick remains because the available evidence did not show a clear link between the remains and the claimant Indian tribes. The DoI and DoA accepted the first determination of the district court, i.e., that cultural affiliation between the remains and the tribes was not supported by a full consideration of the evidence. However, the government appealed the part of the district court ruling that NAGPRA did not apply to ancient human remains found within the jurisdiction of the Ninth Circuit Court of Appeals. Rather, the government argued that the archaeological, chronological, contextual, and taphonomic evidence developed by the government's scientific examinations and tests indicated that the remains should be considered "Native American" within the meaning of the term in NAGPRA.

The Kennewick Man case in federal court, which began in October 1996, reached its legal conclusion in February 2004, when a three-judge panel of the Ninth U.S. Circuit Court of Appeals issued an opinion supporting the earlier decision of the district court in Oregon (Gould 2004). The circuit court decision emphatically agreed with the district court opinion that in order for NAGPRA to apply to a set of Native American human remains, the remains must "...bear some relationship to a *presently existing* tribe, people, or culture to be considered Native American" (emphasis in original; Gould 2004: 1596). The circuit court, again in support of the district court, stated that the facts about the Kennewick Man skeleton could not reasonably be construed to provide such a link to any of the modern tribes or Indian groups who claim a relationship with the remains. The court went on to generalize from the specifics of the Kennewick case, noting that the scientific excavation, investigation, and study of ancient human remains that are unrelated to modern American Indians are neither a target of the law nor precluded by NAGRPA (Gould 2004: 1598).

The Ninth Circuit Court decision provided some detail about the kind of a relationship that might serve as a threshold for other situations. In other words, how much of a relationship and what kinds of relationships should exist for a set of remains to pass into the "Native American" category and thus be subject to NAGPRA? The opinion notes:

> ...though NAGPRA's two inquiries have some commonality in that both focus on the relationship between human remains and present-day Indians, the two inquiries differ significantly. The first inquiry [i.e., asking whether human remains are Native American] requires a general finding that [human] remains have a significant relationship to a presently existing 'tribe, people, or culture,' a relationship that goes beyond features common to all humanity. The second inquiry [i.e., asking which American Indians or Indian tribe bears the closest relationship to Native American remains] requires a more specific finding that [human] remains are most closely affiliated to specific lineal descendants or to a specific Indian tribe. (Gould 2004: 1599)

The circuit court reviewed the evidence collected and used by the government in the case, in particular, the conclusions that the Secretary of the Interior had drawn for the evidence. The court found that the Secretary's interpretation had inadequate factual support for the remains being either Native American or culturally affiliated with the claimant tribes (Gould 2004: 1603 ff.). The court noted that the Secretary overlooked evidence for a lack of connection or cultural continuity between the ancient remains and the modern tribes that his own experts had pointed out. The Secretary relied upon interpretations of tribal oral history accounts to reach his decision that the Kennewick remains were both Native American and culturally affiliated. The court found this evidence unpersuasive concluding that:

> . . .these accounts are just not specific enough or reliable enough or relevant enough to show a significant relationship of the Tribal Claimants with Kennewick Man. Because oral accounts have been inevitably changed in context of transmission, because the traditions include myths that cannot be considered as if factual histories, because the value of such accounts is limited by concerns of authenticity, reliability, and accurate, and because the record as a whole does not show where historical fact ends and mythic tale begins, we do not think that the oral traditions. . .were adequate to show the required significant relationship of the Kennewick Man's remains to the Tribal Claimants. (Gould 2004: 1607)

The court acknowledged the legitimacy of oral and traditional histories and evidence as one kind of information used to answer the inquiries that NAGPRA poses. However, in the Kennewick case, the court found this evidence irrelevant and misinterpreted by the DoI.

More Legal Developments, Additional Studies, and Final Treatment of the Kennewick Man Remains

Following the Ninth Circuit Court decision, in 2004 and 2005, legislation was proposed by the Senate to amend NAGPRA to ease the need to demonstrate in detail that Native American human remains or objects are related to a current, federally recognized tribe in order for the remains to be subject to the law and regulations. The NAGPRA Review Committee annual report for 2006 endorsed this approach. However, in the House of Representatives, a bill designed to focus the intent of NAGPRA on remains for which clear tribal affiliation could be determined was introduced in 2006. Neither of these legislative approaches to clarifying appropriate implementation of NAGPRA on this matter moved any further in Congress.

Following the conclusion of the federal legal case, the CoE worked with the plaintiffs, whose request to study the Kennewick remains was approved as part of the federal court decisions, to plan and undertake another physical study of the remains. Researchers associated with the plaintiffs in the federal case examined the Kennewick Man remains in July 2005 and February 2006. Nearly a decade later, the large (650-plus page) report about these examinations and subsequent analysis of the measurements and observations was published (Owsley and Jantz 2014). Shortly after this publication, Rasmussen, with a large number of coauthors, reported a successful extraction and subsequent analysis of ancient DNA from a bone sample from the Kennewick skeleton (Rasmussen et al. 2015; Meltzer 2015). The study results showed a:

> . . .stronger association of the Kennewick man with Native Americans than with any other continental group. We also observe that the autosomal DNA, mitochondrial DNA and Y-chromosome data all consistently show that Kennewick Man is directly related to contemporary Native Americans, and thus show genetic continuity within the Americas over at least 8 thousand years. Identifying which modern Native American groups are most closely related to the Kennewick Man is not possible at this time, since our comparative DNA database of modern peoples is limited, particularly for Native American groups in the United States. . .among the groups for which we have sufficient genomic data we find that the Colville, one of the Native American groups claiming Kennewick Man as ancestral, show close affinities to that individual or at least to the population to which he belonged. (Rasmussen et al. 2015: 458)

Perhaps this additional and independent piece of evidence would have persuaded the district and circuit courts that Kennewick Man was "Native American" for the purposes of NAGPRA, as the 1998–2000 DoI studies had inferred. However, the case was closed, and there may have been little interest in opening it again or starting a new case to see if this additional evidence would make a difference. In addition, having the remains determined to be Native American only meant that NAGPRA would apply to their treatment and disposition. Such a determination would not resolve automatically to which tribe or group of tribes the remains should be turned over. In most cases, a determination of "cultural affiliation," which requires that there be a "relation of shared group identify" between Native American human remains and a claimant Indian tribe, is required to justify the return of remains to a

tribe. In the Kennewick Man case, the district court, affirmed by the appeals court, had determined that the available evidence did not merit a determination of cultural affiliation between the Kennewick Man remains and the claimant tribes.

Following the publication of the Rasmussen et al.'s ancient DNA study and the wide publicity of the findings, the CoE funded a second ancient DNA study. The primary aim of the second study (Novembre et al. 2016) analysis was to provide an independent validation of the genetic evidence underlying the Rasmussen et al. study and its interpretations. The Novembre et al. study results concurred with the findings of the earlier study. The 2016 report notes that the sample tested is genetically closer to modern Native Americans than to any other population worldwide. Several distinct analyses that were part of the investigation support this conclusion. The authors note that their investigation spanned three non-overlapping subsets of the data and that each distinct result was consistent with Native American ancestry.

In 2016, the CoE Northwestern Division office, which retained legal responsibility for the care of the Kennewick remains, reviewed the evidence about the remains from the reports prepared by the DoI, as well as the ancient DNA evidence from the 2014 to 2016 studies. The Division Commander, Brigadier General Scott A. Spellmon, formally determined that for the purposes of compliance with NAGPRA, the Kennewick Man skeletal remains should be considered "Native American." The 14-page report (Spellmon 2016) describes the information and research results that support this determination.

Rather than rely upon a new case in the federal court system or amendments to NAGPRA to resolve these thorny matters, Senator Patty Murray of Washington and Representatives Newhouse, Heck, Kilmer, and Walden introduced in 2015 and 2016 legislation requiring that the CoE return the Kennewick remains to the claimant tribes. In December 2016, President Obama signed legislation requiring the return. On 17 February 2017, at the Burke Museum in Seattle, the remains were handed over to representative of the tribes (Inslee 2017). Early the next morning at a secret location near the Columbia River, Kennewick Man, the Ancient One, was reburied by tribal members.

Future and Ongoing Considerations

Opinions differ on the interpretation of evidence and the law in the complex and unusual case of the Kennewick Man. This case was surrounded with controversy from the very beginning. Numerous perspectives have been expressed on the various administrative, legal, and scientific aspects of the case as it worked its way through the federal court system and since. In addition to the analyses and interpretations about the skeletal remains, the Kennewick case generated discussion and written opinions regarding the study and treatment of human burials and remains from archaeological sites; the appropriate balance between humanistic, cultural, and scientific investigation; and the appropriate interpretations of ARPA and NAGPRA (e.g., Bruning 2006; Burke et al. 2008; Colwell 2017; Downey 2000; Owsley and Jantz 2001; Melzer 2015; Swedlund and Anderson 1999, 2003; Thomas 2000; Watkins 2003). These debates and discussions certainly will continue. No doubt the case of Kennewick Man/the Ancient One will be part of such future consideration. For the present, at least, the remains are reinterred and that aspect of the case has been determined.

K

Kent, Susan

Wendy Ashmore
Department of Anthropology, University of California, Riverside, CA, USA

Basic Biographical Information

Thoroughly engaged in anthropology, ethnoarchaeology, and social activism, Susan Kent (1952–2003) was born on 26 June 1952 in Oakland, California, and passed away on 12 April 2003 while attending the annual Society for American Archaeology meeting in Milwaukee, Wisconsin. Educated at the University of Southern Colorado, Pueblo, Colorado (B.S. in Anthropology, 1973), and Washington State University

(M.A., 1975; Ph.D., 1980, both in Anthropology), she held visiting faculty appointments at the Universities of New Mexico, Iowa State, and Kentucky before joining the faculty at Old Dominion University, Norfolk, Virginia, in 1986. In 2000, Old Dominion honored Kent as Eminent Professor of Anthropology.

Major Accomplishments

From the outset of her career, Kent challenged herself, as well as her colleagues, to think across disciplinary boundaries and theoretical perspectives and to value the insights such intersections could produce. Indeed, she sought to communicate with and involve notably diverse groups – anthropologists and other social scientists, as well as architects, medical practitioners, people who set government policies, and multiple publics. For presenting her arguments, she set great store by the power of sound statistical analysis, necessarily grounded in carefully gathered evidence sets and critically assessed (1984). At the same time, she appreciated the importance of qualitative differences within and between cultures and the impact of social, political, and economic circumstances on both observer and observed. Kent had a pronounced positive impact in and beyond her field. An edited volume honoring her life and legacy offers a multivocal critical review of her diverse career-long contributions and continuing influence (Ashmore et al. 2006).

The research for which she is best known is ethnoarchaeology, the study of living peoples and their customs with special attention to the archaeologically observable material traces of these societies and cultures. Originally treated by most as a methodological tool to improve the reliability and richness of archaeological inference, ethnoarchaeology has become much broader as a field of intellectual and practical inquiry. In this scientific and interpretive blossoming, Kent was long a recognized leader.

Initially, her work focused on ethnoarchaeological study of spatial organization, especially in activity areas. Drawing from her research on domestic spatial arrangements in three present-day cultures of New Mexico (1984), she became a strong advocate for cross-cultural and interdisciplinary inquiries and for developing theory and methods for activity area studies (1987). These early books remain critical sources for ongoing research in ethnoarchaeology and spatial studies. By 1987, she was already conducting research in the Kalahari, among the Bajarwa ("bushmen," San), laying the interpersonal and scientific foundations for her enduring close involvement with people and cultures of southern Africa.

Kent viewed her studies of life among the Bajarwa in Botswana, Navajo, Hispanic, and Euro-American communities in the western United States, and with other peoples and cultures, as yielding insights for a broad range of significant social, medical, anthropological, and archaeological questions. These include, but are far from restricted to, the social meaning and implications of domestic spatial organization (1990); the causes and structure of sedentism and residential mobility (1989, 1996); the articulation of sedentism, diet, demography, and health (Stuart-Macadam and Kent 1992); the impetus and constraint to gender differentiation in distinct societies, especially in Africa (1998); and a wide array of topics on social justice (2002). Prominent among her enduring concerns were efforts to recognize and rectify inequalities in health, gender relations (1998), and relations between hunter-gatherer and farming societies, especially as these are now further encompassed in modern nation states (1989, 1996, 2002).

Working directly with hunter-gatherer and middle-range societies, Kent actively fomented debate on such critical issues as the autonomy and subordination of hunter-gatherers today and the diversity of customs within and between groups, now and in the past. Egalitarianism and sedentism are recurring themes in her published statements. The foregoing concerns are evident consistently in her numerous articles and book chapters and more especially in the volumes she edited, calling on colleagues with varying perspectives to engage cross-culturally the issues she posed (1989, 1996, 2002). Although not all her colleagues agreed with her every argument, Kent was undeniably a key contributor to the

research discourse and dedicated to bringing out the best models and inference from the collective research endeavor, especially for benefit of the people from whom scholars and policy makers learned.

As Rosen and colleagues note: "She staunchly believed in the equality of all peoples and in the dignity of individuals—most especially those who for decades informed her work and enriched her life.... [she contended that] anthropologists should lead the way in informing policy-makers about the plight of indigenous populations who might not be granted a voice of their own" (2006: 1). As archaeologist, ethnoarchaeologist, anthropologist, and activist, Susan Kent was an original thinker and prodigious researcher, beginning new high points in her productive career when her work came to an abrupt, unforeseen halt. Kent's final research project returned her to archaeological fieldwork about Middle-to-Late Stone Age activity areas and paleoenvironment in South Africa; a book manuscript on avoiding pitfalls of incautious statistical inference was under review; and the new book in progress at her death was a decade-long review of egalitarianism and sedentism in Botswana.

Kewibu, Vincent

Matthew Leavesley
School of Arts and Social Sciences, James Cook University, Cairns, QLD, Australia

Basic Biographical Information

Vincent was born on January 28, 1972, in Didiwa village in the Rabaraba District of Milne Bay Province, Papua New Guinea (PNG).

He is the second born son of John and Joyce Kewibu who are subsistence farmers. His paternal grandfather (Lawrence Irimoai) died during WWII while working as a carrier for the Australian forces primarily between Buna and Kokoda. He attended Korkoyabagira Community School before moving to Martyr's Memorial High School in Popondetta (Oro Province).

He finished his Grade 12 exams at Sogeri National High School in 1991 before entering undergraduate studies in Education at the University of Papua New Guinea (UPNG) in Port Moresby. After having completed his first year at UPNG, he switched across to archaeology and completed his B.A. in 1995. While studying at UPNG, he participated in research projects investigating trade and exchange at Woodlark Island with Simon Bickler and agriculture in the highlands of PNG at Kana with John Muke and Jack Golson. In 1997, he was awarded a scholarship to study archaeology at La Trobe University in Melbourne, Australia.

Major Accomplishments

During his candidature he participated in a number of research projects including the survey for European gold rush and contemporary Aboriginal archaeological sites at the Howqua Hills in Eastern Victoria with Susan Lawrence and Richard Cosgrove. He also participated in excavations at the Marki Alonia site in Cyprus run by David Frankel and Jenny Webb. He graduated from La Trobe University with a B.A. (Honors) in 1999. His Honors project focused on notions of trade and exchange as they apply to the archaeological predicates of the ethnographically recorded Hiri trade and exchange system that existed on the Papuan Coast of PNG.

Upon completion of his undergraduate studies, he returned to UPNG to take up a position as Tutor in Archaeology. During this time, he participated in survey and excavations in the Talasea region of West New Britain Province, PNG, run by Robin Torrence (Aust Mus), Peter White (U of Syd), and Jim Specht (Aust Mus). This project was broadly focused on prehistoric human adaptations to natural disasters.

In 2001, he was promoted to Lecturer in Archaeology at UPNG. At this time, his attention turned to cultural heritage management issues related to the dissemination of archaeological research into village-based rural communities. Between 2001 and 2003, he contributed to three separate workshops held across the New Guinea Islands region in Kavieng, Lorengau, and Buka coordinated by Glenn Summerhayes (Otago).

In 2004, he was awarded another scholarship, this time to attend the Australian National University (ANU) in Canberra. His research focus returned to issues of trade and exchange; however, this time, his case study was the Massim region of SE Papua (PNG). In particular, he focused on establishing an archaeological connection between the Trobriand Islands and mainland New Guinea by undertaking investigations on the D'Entrecasteaux Island Group, specifically, West Fergusson, Dobu, and SE Goodenough Islands.

Upon his return to UPNG in 2006, he has participated in various projects. These include investigations into the paleoenvironment of the

Port Moresby region with Simon Haberle (ANU). The Port Moresby Region Hilltop Survey Project based at UPNG, for example, seeks to investigate when and why populations appear to have used these apparently less hospitable locations. He also participated in the ongoing Caution Bay Project (a collaboration between Monash University and UPNG) that seeks to investigate notions of the Motuan expansion along the Papuan Coast and subsequent rise of the Hiri trade and exchange network.

Khok Phanom Di, Archaeology of

Charles F. W. Higham
Department of Anthropology and Archaeology, University of Otago, Dunedin, New Zealand

Introduction

Khok Phanom Di is a deeply stratified prehistoric mound located on the eastern margin of the Bangkok Plain in Thailand. Excavations in 1984–1985 (Higham and Thosarat 2004) in an area of 100 m ^{2} revealed a stratigraphic sequence 7 m-deep. The cultural buildup incorporated shell middens, occupation and industrial remains, and human inhumation graves. The radiocarbon determinations indicated that the site was occupied between approximately 2000 and 1500 cal. BCE (Fig. 1).

Definition

The second millennium BCE was a most significant period for Southeast Asian prehistory. In 2000 BCE, the area was occupied by hunter-gatherers whose ancestors had arrived from an African homeland at least 50,000 years ago. Over the ensuing five centuries, the indigenous hunter-gatherers interacted with intrusive groups of rice and millet farmers expanding south from the Yangtze and Yellow River valleys of China (Rispoli 2008; Zhang and Hung 2010). In the eleventh century, the now established farming communities entered the Bronze Age, and social changes took a dramatic turn (Higham et al. 2011).

Key Issues

Khok Phanom Di is a key site in illuminating what happened during the first half of this second millennium BCE. The unusual survival of organic remains, linked with the flotation to recover plant and microfauna, has led to the reconstruction of a detailed environmental history. The first occupants occupied an estuary when the sea rose significantly above its present level. The analyses of the plant remains, forams, ostracodes, and shellfish are unanimous in reconstructing a mangrove shore that persisted through the first three of seven mortuary phases (Fig. 2) that demarcate the site's cultural sequence (McKenzie 1991; Mason 1996; Thompson 1996). The tropical estuary is one of the richest habitats known in terms of bioproductivity, and during this period, the occupants of the site harvested the fish, crabs, and shellfish but showed no signs of cultivating plants or maintaining domestic animals. Although the initial occupation of Khok Phanom Di was by marine hunter-gatherers, the site almost at once

Khok Phanom Di, Archaeology of,
Fig. 1 The calibrated radiocarbon determinations and spans based on charcoal from Khok Phanom Di, following the application of an outlier model which specifies charcoal and gives an exponential tail to the data, saying effectively that it is more likely to be older than younger

attracted Neolithic farmers who brought with them their preferred pottery industry that involved complex incised and impressed designs, as well as finely polished stone adzes. The estuarine habitat, however, was not suited to rice cultivation, and although some fragments of rice were found in early contexts, it was the exotic imported pottery that were actually tempered with rice chaff. Thus, the initial farmers concentrated on hunting, gathering, and fishing at the expense of farming.

With mortuary phase 3B, there was a dramatic change in the environment, involving a sharp rise in freshwater indicators compatible with a decline in the sea level. At this juncture, we find that some women came to the site from a different habitat (Bentley et al. 2007), while rice harvesting knives and granite hoes were used. The remains of partially digested food found in the stomach area of a woman contained domestic rice chaff and freshwater fish scales and bones. This period, which probably dates to the eighteenth century BCE, clearly witnessed the establishment of rice cultivation, which persisted into mortuary phase 4. However, with mortuary phases 5–7, marine conditions returned, and no further harvesting knives or granite hoes were found.

Khok Phanom Di, Archaeology of, Fig. 2 The layout of the mortuary phases 2–6 at Khok Phanom Di

K

The rapid accumulation of cultural remains at the site, which included the deposition of thick shell middens, has resulted in a remarkable mortuary sequence in which the dead were interred over the ancestors. This has allowed the reconstruction of about 20 generations over a period of five centuries, leading in turn to a detailed exposure of social changes over time. The earliest occupants of Khok Phanom Di buried the dead in shallow graves, within their middens. A child was found interred in a fetal, crouched position, while two men and a woman were placed extended, on their backs with the head directed to the east, one accompanied by a handful of shell beads. Two of the adults and the child exhibited bone conditions that suggested that they suffered from a blood disorder that, while shielding the individual from malaria, caused anemia. This genetic disorder may well reflect many generations of survival in a malarial environment (Tayles 1999).

The second mortuary phase reveals a marked change in the treatment of the dead, for they were now interred in tight clusters, laid out on a checkerboard pattern, still with the head to the east. In some cases, mineralized wood under the skeleton suggested that they were placed on a bier, and to add to the increasingly complex rituals that attended funerals, bodies were sprinkled with red ocher and wrapped in a shroud of asbestos sheets. Mortuary offerings now included brilliantly polished and decorated pottery vessels. One man stood out for his lavish ornaments that included 39,000 shell beads. Cowrie shells were also found as mortuary offerings, as well as a rhinoceros tooth and bangles fashioned from fish vertebrae. The layout of the burial clusters was complemented by a thick shell midden that ran between them and even turned at right angles, as if it had accumulated against a structure of some sort. This, combined with the presence of the holes that would once have held the upright posts of a building, strongly suggests that there had once been mortuary buildings to contain the dead.

The study of the bones themselves reveals a very high proportion of newly born infants. The adults, many of which continued to exhibit symptoms of anemia, had well-developed bones with robust musculature, which Tayles (1999) has suggested might have been the result of such activities as paddling canoes, or kneading and converting clay into pottery vessels. All the skulls analyzed were closely related in form to other intrusive farmers, and beyond to the early rice cultivators of the Yangtze Valley.

The third mortuary phase continued in the established tradition of interment in tight groups lying over the ancestors, associated with finely made pottery vessels and shell jewelry. Half of all graves also continued to contain newly born infants. However, during the course of this phase, there were also a series of important changes seen in the adoption of rice cultivation. A few dog bones were also found, but no other domestic animals. The presence of the dog is significant, for it must have been brought into Southeast Asia from an exotic source, probably China.

During mortuary phase 4, the freshwater indicators continued, and there was a marked drop in infant mortality, but four of the five children encountered had suffered from severe anemia. Men were physically less robust than their predecessors, and they were increasingly distinguished from women when interred: men were found with large, fractured ornaments fashioned from turtle carapaces, whereas women were accompanied by the anvils and burnishing stones used to manufacture and decorate pottery vessels. But with the reversion to marine hunting and gathering during mortuary phase 5, there was a profound change in the rituals of death. In place of the traditional groups, we find a single grave far larger than was necessary to contain the body of the woman within it (Fig. 3). She had been interred in upper garments embellished with over 120,000 shell beads. There were shell discs on her chest, shell ear ornaments, and a shell bangle. Her body had been covered in red ocher and laid under a pyramid of clay cylinders destined to be converted into pottery vessels. Several completed vessels, each a masterpiece, were laid beside her, and by her right ankle, there was a potter's anvil and a shell containing two well-used burnishing stones. This staggering

Khok Phanom Di, Archaeology of, Fig. 3 Burial 15, of mortuary phase 5. This woman was interred with a remarkable amount of shell jewelry including over 120,000 shell beads

mortuary wealth was matched by that associated with an infant, not yet two years old at death, in an adjacent grave. Again, there were clay cylinders heaped over the body with thousands of shell beads, a shell bangle, fine pots, but also a miniature clay anvil placed beside the infant's right ankle. It is hard not to identify this woman as a master potter, particularly given the strong musculature of her wrists, and the infant as her daughter, a future potter who suffered a premature death. Her wealth might well have been due to her expertise in manufacturing vessels for exchange that brought to the site, exotic shell from a coralline environment.

Although the absolute amount of wealth fell back with the ensuing phase 6, rituals were still intense, for two women and a child were found buried within a raised mortuary chamber with clay wall foundations and floor. They wore thousands of shell beads and again, were accompanied by their clay anvils. In front of them, however, enclosed within a wooden building, was a row of graves containing men and women, as well as newly born probable twins, with much more modest offerings. A lively discussion could be generated from this information, as to whether this hunter-gatherer society was now divided into rich and poor social groups. However, after a handful of scattered burials representing mortuary phase 7, the sequence spanning perhaps as many as 20 generations came to an end.

Current Debates

The presence of the sophisticated ceramics and polished stone adzes indicate that the inhabitants of Khok Phanom Di were immigrant rice farmers who, on reaching a coastal habitat that was not conducive to cultivation, became hunter-gatherers (Bellwood and Oxenham 2008). Initially they encountered local hunter gatherers whose the material culture is a mirror image of that from an earlier coastal settlement of Nong Nor, located only 22 km to the south, and dated to the mid third millennium BCE. There are numerous similar Neolithic sites in Vietnam, and early farmers probably along the coast. It is most unlikely that this was the only migratory route south, other farmers probably following the course of the Mekong and Salween rivers.

Future Directions

No comparable site to Khok Phanom Di is known. Only a tiny fraction of the mound has been excavated. Future research should be directed to finding more settlements along the raised shoreline of the Gulf of Siam, while opening up by excavation more of Khok Phanom Di to identify its internal structure and layout.

Kiik-Koba Grotto: Significance for Paleolithic Studies in East Europe and the Former Soviet Union

Yuri E. Demidenko
Crimean Branch, Institute of Archaeology, National Ukrainian Academy of Sciences, Simferopol, Crimea, Ukraine

Introduction

Kiik-Koba grotto and its finds, including Neanderthal remains, occupy a special place not only in the Crimean Paleolithic. Their significance for Paleolithic studies in East Europe and the former Soviet Union in general is impossible to exaggerate. Its excavations in the 1920s and subsequent publication had a significant influence on trends in Paleolithic archaeology in this part of the Old World for many years (see Bonch-Osmolowski 1940), due to the scientific rigor of Gleb A. Bonch-Osmolowski of then Leningrad. According to Gladilin, his scientific works "entered into the Golden Fund of Soviet and World-wide archaeological science and till now remain exemplary" (Gladilin 1985).

The grotto is situated on the right bank of the Zuya river 120 m above the river's modern water level, in a rocky massif of Jurassic limestone, within the northern spurs of Dolgorukovskaya

Yaila, part of the first ridge of the Crimean Mountains in Eastern Crimea, about 25 km east of Simferopol and 7 km south of Zuya. The grotto's niche (Fig. 1) is quite large: 11 m wide, 9 m deep, and 9 m high and faces southeast.

Key Issues/Current Debates/Future Directions/Examples

Discovery, Excavations, and Stratigraphy

The grotto was discovered by Bonch-Osmolowski in 1924 but known to local Tatars as "Kiikin-Kobasy" (Savage's Cave) or "Kiik-Koba" (Wild Cave). The latter name was chosen by Bonch-Osmolowski.

Excavations were carried out in 1924 and 1925, while 1926 was devoted to two trenches on the slope outside the drip line, where Paleolithic artifacts were rare or absent. During a test excavation (1.5 m^2, see Fig. 1 – sq. 2), two brownish-gray/almost black *hearth layers* (stratigraphic layers IV and VI or upper and lower archaeological layers, respectively) with flint artifacts and animal bones were identified within a sequence less than 1 m thick. The deposits were mainly clayey and loamy with a varying number of limestone *eboulis*. The *lowerhearth layer* was near bedrock, separated from it only by thin clayey layer VII. The dark color of *hearth layers* was due to multiple overlapping of hearths/fireplaces from different human occupation events and subsequent ablution and mixture during human activity into dark ashy depositional components. After the test sondage was dug, the site was spatially mapped using a 1×1 m^2 numerical grid system (Fig. 1) and several datum points were established for elevation measurements. Two Neanderthal burials were discovered in 1924. The 1925 excavations concentrated documentation of the stratigraphic and structural features of the two archaeological layers over as large an area as possible. In total an area of 60 m^2 was excavated. Limits of each arcaheological layer within the grotto were identified, enabling Bonch-Osmolowski to consider many aspects of human settlement. The excavations concluded with sample collection for later laboratory studies: charcoal and burnt bone fragments and a sediment column sequence (0.2 m wide and almost 1 m thick) from square 41. All lithics and animal bones, including the smallest items collected by dry sieving through 1-cm mesh screens, were transported to Leningrad. Many stratigraphic profiles and sedimentary features were drawn and photographed. Indeed, the Kiik-Koba excavation documentation is quite similar to modern standards, with description cards for nearly all excavated squares and recording of stratigraphic and planographic data. This information allowed Bonch-Osmolowski himself, many of his contemporaries, and later colleagues to propose various interpretations of different aspects of the site.

Archaeology and Chronology

Many archaeological and chronological interpretations of the archaeological layers at Kiik-Koba have been proposed over the more than 80 years since the site's first excavations.

Lower Layer

Bonch-Osmolowski (1940) considered the layer's assemblage, with almost 13,000 flints, (Fig. 2) as "an amorphous stage of Pre-Chelleen," finding that "the most similar . . . assemblages appear only far away in the West, in the lower layers . . . of La Ferrassie, La Micoque and Le Moustier," as well as the lower layer at Tabun Cave in Palestine and "numerous . . . horizons of alluvial find spots with Pre-Chelleen, Old Clactonian, 'Tayacien' and other atypical artifacts" having "the same absence of definite tool types, connected to a primitive variety of both the same massive primitive debitage and rough, denticulated edge retouch." With respect to dating, Bonch-Osmolowski first attributed the lower layer to the "Last Interglacial epoch" (1934) but then proposed a considerably older position in "an Interglacial period preceding the Maximum (Riss) Glacial time" (1940) or even the "beginning of Mindel-Riss" (1940).

Kiik-Koba Grotto: Significance for Paleolithic Studies in East Europe and the Former Soviet Union, Fig. 1 Kiik-Koba grotto. Plan and stratigraphy. (**a**) Excavation plan. (Modified after Bonch-Osmolowski 1940: Fig. 10) *1* – limestone blocks in modern lithological layer I; *2* – limits of lithological layer II; *3* – the grotto's drip line. (**b**) The grotto's longitudinal stratigraphical profile from northwest to southeast through the grotto's central line. (Modified after Bonch-Osmolowski 1940: Fig. 11) *1* – Holocene lithological layer I; *2* – gray limestone loamy sand with some "Tardenoisian" finds; *3* – lithological layer III; *4* – lithological layer IV (upper hearth layer); *5* – lithological layer VI (lower hearth layer); *6* – clay lenses

At the start of the 1950s in Soviet archaeology, the layer was considered to be Late Acheulian–Early Mousterian.

Since the late 1960s, Gladilin viewed this assemblage as a sort of Tayacian-like Denticulated Micro-Mousterian (Gladilin 1966, 1976, 1985). Also, given the presence of only Upper Pleistocene animal species, the lower layer was attributed to the end of Riss/beginning of Riss-Würm or Riss-Würm/beginning of Würm in the mid-1960s. Gladilin (1976) later noted stadial period sediment and pollen for both lower and upper layers at Kiik-Koba and proposed two chronological phases for the lower layer – "either . . . Riss II or . . . an initial phase of Würm I." Since the early 1970s, the Denticulated Micro-Mousterian industrial attribution became widely accepted among Paleolithic archaeologists.

It was only in the early 2000s that another assemblage similar to the Kiik-Koba lower layer was found in the Crimea: Starosele, level 3 after the 1990s excavations (Demidenko 2003–2004). Starosele, level 3, is geochronologically attributed to the Lower Pleniglacial of the Last Glacial (MIS 4), c. 70,000 BP (Chabai 2004), which also appears comparable to the pollen data for the Kiik-Koba lower layer. Such comparisons between Kiik-Koba and Starosele have opened

Kiik-Koba Grotto: Significance for Paleolithic Studies in East Europe and the Former Soviet Union, Fig. 2 Kiik-Koba, lower archaeological layer. Flint artifacts. (**a**) Cores – *1* – *2* – primitive parallel cores; *3* – discoidal core. (Modified after Bonch-Osmolowski 1940: Table I). (Modified after Bonch-Osmolowski 1940: Tables I, VI – IX)

new doors for research on this Early Last Glacial Middle Paleolithic industry type in Crimea.

Upper Layer

Bonch-Osmolowski (1940) compared this assemblage, with c. 4,700 flints (Fig. 3), to the Micoquian from the eponymous French site and chronologically attributed it to the end of the Lower Paleolithic/beginning of Mousterian (Middle Paleolithic in modern terminology). He connected it to the "Late Micoquian, . . . very end of the Acheulian stage on its transition into Mousterian" (Bonch-Osmolowski 1934) or to the "end of the Acheulian or . . .to the transition from Acheulian to Mousterian" (Bonch-Osmolowski 1940). In his view, there was a group of similar Late Acheulian complexes in the Old World (e.g., La Micoque, upper layer in France, Okiennik and Nad Galonska in Poland, Koesten and Klausennische in Germany, Tabun Cave, layer E in Palestine) with "a combination of Mousterian unifacial tools and bifacial hand axes of Late Acheulian type" (Bonch-Osmolowski 1940). Similar complexes were also identified by him in the Crimea (Volchiy grotto, Chokurcha, Adzhi-Koba Cave, lower layer) and in the Northern Caucasus (Ilskaya). Initially, Bonch-Osmolowski attributed the upper layer "to the end of the Last Interglacial or to the beginning of the Last Glacial" (1934) but then considered it to be much older – to "a dividing line" between Mindel-Riss and Riss (1940).

In the 1950s, however, Soviet colleagues attributed the upper layer assemblage to the Mousterian and even to a sort of Mousterian with Acheulian Tradition.

Since the mid-1960s, based on lithological, faunal and pollen data, the geochronology of the Kiik-Koba, upper layer was discussed in terms of the Upper Pleistocene: either the beginning of Würm or end of Riss-Würm/beginning of Würm.

Gladilin first proposed a "Micro-Mousterian with Acheulian Tradition variant" attribution (Gladilin 1966) but concluded by arguing for the "Kiik-Koba culture of Mousterian period in Crimea" within the "Bifacial Micro-Mousterian variant" (Gladilin 1976, 1985). This was done on not only on the basis of clear differences between the "Bifacial Mousterian in the Russian Plain and Crimea with sites of Mousterian with Acheulian Tradition in France" but also a major culture paradigm shift in Soviet archaeology in the 1970s for understanding all Paleolithic periods (Gladilin 1976). Based on lithological data, Gladilin attributed the upper layer to a stadial period, which is "not older than the first half and not younger than the second half of Würm I," quite congruent with Bonch-Osmolowski's (1940) reconstruction of the prehistoric landscape around the site based on fauna species composition: "a dry grassy steppe with a rather harsh continental climate."

The existence of a "Kiik-Koba Mousterian culture" in Crimea was supported by Yu.G. Kolosov

Kiik-Koba Grotto: Significance for Paleolithic Studies in East Europe and the Former Soviet Union, Fig. 3 Kiik-Koba, upper archaeological layer. Flint artifacts. (**a**) cores – *1* – discoidal core of triangular shape; *2* – orthogonal core of triangular shape; *3* – conventionally parallel transverse core of triangular shape/angle burin; *4* – conventionally parallel transverse core of rectangular shape. (**b**) Tools – *1* – simple convex sidescraper; *2* – transverse convex sidescraper; *3* – transverse convex oblique sidescraper; *4* – convergent sidescraper; *5–8* – unifacial points; *9* – bifacial point; *10* – bifacial sidescraper. (Modified after Bonch-Osmolowski 1940: Tables XI – XIV, XVI – XVII)

(see in Demidenko 2004; Demidenko et al. 2013) in the 1970s and 1980s, after his excavations at Prolom I in the 1970s and comparison of the Prolom I material with Bonch-Osmolowski's and Gladilin's data for the Kiik-Koba, upper layer assemblage. The Kiik-Koba upper layer was attributed by him to the "end of the Early Mousterian, in geological age close to the end of Early Würm I."

The cultural paradigm for the Kiik-Koba materials was developed by V.N. Stepanchuk in the 1990s and 2000s (see in Demidenko 2004; Demidenko et al. 2013). Using the paradigm's concept in which each tool was made intentionally, each Neanderthal tribe had its own industrial tradition, territory, hunting habits, etc.; he constructed the Kiik-Koba culture with a "distinct and syncretic tradition" of either a "para-Micoquian or Charentoid para-Micoquian" or an "atypical Charentian with features of a Micoquian influence" reflecting a "para-Micoquian Kiik-Koba industrial tradition" in the 1990s. Chronologically, the Kiik-Koba culture complexes were placed by him in the 1990s based on the following Last Glacial interstadial period intermittent sequence: Brörup (Kiik-Koba grotto, upper

layer) – Moershoofd (Prolom I grotto, lower layer) – Hengelo (Prolom I grotto, lower layer) – Denekamp (Buran-Kaya III grotto, level 7: 2), lasting from c. 100,000 BP to c. 30,000 BP, about 70,000 years for the Middle Paleolithic. In the 2000s, he radically changed the culture's chronology. After obtaining several new C14 dates for Kiik-Koba and Prolom I, the Kiik-Koba culture chronology became much shorter: the Stadial preceding the Denekamp interstadial and the Arcy interstadial (c. 35–28,000 BP), cultural characteristics remaining unchanged.

Since the mid-1990s a new approach for understanding Crimean Micoquian Tradition sites and find complexes, including Kiik-Koba, upper layer (Chabai et al. 2000; Chabai 2004; Demidenko 2004), was proposed. The Crimean Micoquian Tradition includes three traditionally defined industry types (Ak-Kaya, Kiik-Koba, Starosele). The industry types have the same primary flaking processes (a combination of radial, discoidal, multiplatform and parallel reductions without the Levallois method) and tool types, but tool type proportions differ by industry. Typological differences are connected to different human activities taking place at different sites, related to fauna processing and lithic reduction, as well as distances to high quality flint outcrops. As a result of the highest rates for human activities and the most distant location from flint outcrops, the Kiik-Koba lithic assemblages feature the highest indications of reduction with a medium amount of bifacial tools (c. 15%), an abundance of points among the unifacial (c. 40%) and bifacial (c. 50%) tools, a rather low frequency of simple sidescraper types (c. 20–30%) among unifacial tools, as well as mostly small (less than 5 cm long) bifacial and unifacial tools, which is why the industry was often attributed to the Micro-Mousterian.

Complex reanalyses of the 1920s Kiik-Koba, upper layer lithic assemblage and fauna were recently realized (Demidenko et al. 2013), clarifying the features of this industry type. A chronological position has been proposed in the stadial preceding the Arcy/Denekamp interstadial (Chabai et al. 2000; Chabai 2004; Demidenko 2004; Demidenko et al. 2013).

Kiik-Koba Grotto: Neanderthal Burials

The first burial of a child (Bonch-Osmolowski 1940) was found "in sq. 13, in 30 cm distance to the North from northern corner of another grave pit, which is from head of the adult human." The 5–8-month-old child "was lying in a so-called uterine position, at left side, almost at very bedrock. . . . The skeleton was positioned in a lower portion of VI layer being 15 cm thick at this place. Above, being unclearly separated from it, a so-called inter-hearth layer (Yu. D. –lithological layer V) is not present here, was distributed upper hearth layer, also c. 15 cm thick" (Fig. 4a). The child's "bone preservation is very bad." It was possible "to extract only part of skeleton bones, although most of them were in a defective condition" and "any skull and even teeth were absolutely missing." The grave pit was not traced during excavations. At the same time, the Pleistocene age was definitely established for the skeleton, taking into consideration "non disturbance of all lithological layers above the upper hearth layer and fossilization degree for the child bones." But because "in this place the inter-hearth layer was absent and the upper cultural layer was directly resting on the lower cultural layer, to define stratigraphically the belonging of the child skeleton to one or another layer was not possible." Thus, the layer to which the child burial belonged remained an open question for Bonch-Osmolowski. In the 1980s, Yu.A. Smirnov, using Bonch-Osmolowski's unpublished field notes, reconstructed the stratigraphy of sq. 13 and 14 in detail, showing that the child burial "was done during the existence of IV upper hearth layer and already after deposition of about half of its thickness" and that it was dug into the underlying lower archaeological layer – "in a clay, . . . in one of sub-levels of lithological layer VII" (Smirnov 1991). No indisputable grave goods were identified with the burial, although some unassociated lower layer flints were found when the grave was dug. The Neanderthal morphology for the child skeleton has established (Yakimov and Kharitonov 1979; Trinkaus 2008). As a result, Neanderthals appear to be the makers of the Kiik-Koba industry type of Crimean Micoquian Tradition.

Kiik-Koba Grotto: Significance for Paleolithic Studies in East Europe and the Former Soviet Union, Fig. 4 Kiik-Koba. Neanderthal burials. (**a**) Human burial plans where *shaded* skeleton parts do indicate the ones found during the 1920s excavations. (Modified after Smirnov 1991: Fig. 57; Chabai 2004: Fig. V-4). (**b**) First host/economic pit in sq. 21 and 25 of upper archaeological layer that considerably destroyed the lower layer's adult human burial. (Modified after Bonch-Osmolowski 1940: Fig. 33b)

More well-known Kiik-Koba hominin remains were found in another burial, also Neanderthal, but an adult 40–45 years old (Yakimov and Kharitonov 1979). Unlike the child burial, the adult burial had clearer stratigraphic and spatial features (Bonch-Osmolowski 1940). Although the grave pit was damaged for c. two thirds of its area by a host/economic pit, it had clear ovoid configuration with northeastern–southwestern orientation and size: 2.10 m long, 0.80 m wide, and 0.45 m deep (Fig. 4a, b). The pit was not only stratigraphically related to lower archaeological layer but it was also "cut into the grotto's bedrock," where it was "partially deposited both in a solid limestone and clay pockets." Taking the bone leg position, the human body was placed into the grave "on the right side with slightly bended legs" and by its head to northwest (Fig. 4a). The main problem was the burial's stratigraphy relation to either upper or lower archaeological layer's human occupation. The difficulty was caused by the pit, destroyed much of the grave. Initially, Bonch-Osmolowski (1940) was sure that the burial was made by lower layer humans – "the seemingly clear covering by lower hearth layer of human bones in not disturbed grave pit's part, that has been authentically stated by photo pictures, alongside with common find characteristics, did not leave no doubts that the burial was realized by lower hearth layer people" (see Fig. 4b). But then in the same 1940 book, Bonch-Osmolowski changed

his opinion connecting the adult burial to upper layer humans. "Indeed, it very hardly agrees with a common conception on a historical development of Old Paleolithic Man in combination with such the primitive material culture and such the perfect burial type. The burial seems to be more appropriate for upper hearth layer humans." Moreover, in doing so, Bonch-Osmolowski (1941) also suggested that Kiik-Koba child burial also belongs to upper layer because of "general considerations on a simultaneous burial probability for mother and child" close one to another at Kiik-Koba grotto. All these Bonch-Osmolowski's contradictory notes and hypotheses were in details analyzed by V.N. Gladilin. He certainly concluded that the initial Bonch-Osmolowski's opinion was correct and the adult burial belongs to human occupation of lower layer (Gladilin 1979).

So, now it is almost universally accepted among the ex-USSR archaeologists that the adult burial is related to lower layer and the child burial is associated with upper archaeological layer at Kiik-Koba grotto. And again, all the 1970s and 1980s new analyses on the Kiik-Koba human burials were only possible thanks to the detailed published and unpublished Bonch-Osmolowski's field observations.

Kim, Nam C.

Nam C. Kim
Department of Anthropology, University of Wisconsin-Madison, Madison, WI, USA

Basic Biographical Information

Nam C. Kim received a Ph.D. in Anthropology from the University of Illinois at Chicago, a M.A. in Political Science from New York University, and a B.A. in International Relations from the University of Pennsylvania. Prior to a career in anthropology, he worked in the private and non-profit sectors. He is an anthropological archaeologist in the Department of Anthropology at the University of Wisconsin-Madison.

Major Accomplishments

Much of Dr. Kim's work has been dedicated to ancient state formation, social complexity, and various factors for social change including warfare, trade, and various leadership strategies. He has performed fieldwork in Belgium (Neolithic village fortifications of the Linearbandkeramik culture), the southeastern USA (historic Native American Creek site), and Mesoamerica (postclassic and historic Mayan sites).

Most recently, his research has been geographically focused on East and Southeast Asia, specifically Vietnam, and he has been conducting investigations at the site of Co Loa in the Red River Delta of northern Vietnam. Kim was the first foreigner allowed to collaborate on excavations at the site, codirecting investigations with colleagues at the Vietnam Institute of Archaeology of the Vietnam Academy of Social Sciences. Nam Kim is an honorary member of the Vietnam Institute of Archaeology.

The Co Loa Middle Wall and Ditch Project (2007–2008) was the first full-scale, systematic investigation of the site's monumental system of earthen enclosures. The collaborative research at Co Loa is ongoing and aims to augment an overall understanding of the site's emergence as an early urban center and political capital for proto-Vietnamese civilization during the Iron Age. The research has been funded by various institutions and organizations, including The Henry Luce Foundation, the American Council of Learned Societies, the American Philosophical Society, the National Science Foundation, the George Franklin Dales Foundation, the University of Illinois at Chicago, and the University of Wisconsin-Madison.

The investigations at Co Loa have provided new data that Kim has presented at a variety of conferences and invited lectures in the USA and Asia, including the Society for American Archaeology, the Association for Asian Studies, the Indo-Pacific Prehistory Association, and the Archaeological Institute of America. Research findings have also been disseminated through journals such as *Antiquity*, *Journal of Archaeological Research*, and *Khao Co Hoc*. The research will also be featured in a book currently being written by Kim on the origins of the ancient state in Vietnam. Kim is also working with colleagues in Vietnam's Conservation Center for the Co Loa and Hanoi Citadels (also known as the Hanoi Ancient Wall-Co Loa Vestiges Preservation Center) in efforts related to cultural heritage management. Objectives include obtaining UNESCO World Heritage Site status for Co Loa, as well as the promotion of education, outreach, and global understanding regarding the site's history and cultural significance for Vietnam.

Kimberley Rock Art

Sam Harper[1], Peter Veth[2] and Sven Ouzman[1]
[1]Centre for Rock Art Research + Management, University of Western Australia, Perth, WA, Australia
[2]Oceans Institute, University of Western Australia, Crawley, WA, Australia

Introduction

This chapter summarizes the current state of rock art research in the Kimberley, Western Australia,

which is a globally significant corpus of tens of thousands of rock art, archaeological, ethnographic, and contemporary sites. We present a history of rock art research in the region, discuss linguistic and cultural diversity, across the Kimberley, and outline the development of rock art stylistic sequences and spatial analysis. A new generation of scientific dating of the art and associated excavations is also harmonized. Aboriginal ontologies and recorded ethnography associated with the rock art are highlighted. We also present land tenure land management under native title and affiliated ranger groups as heritage management challenges and opportunities.

Definition

The Kimberley is a biogeographical and cultural landscape covering 423,517 km^2 of northwest Australia. The landscape is marked by massive waterways and river systems, which once continued onto the now-submerged Sahul Shelf, meaning the Kimberley was almost twice its current size during the Last Glacial Maximum 26–19 thousand years ago. This large geographical area has been continuously occupied by people for over 50,000 years by multiple cultural and linguistic groups (Wood et al. 2016; Veth et al. 2019). The Kimberley is part of the non-Pama-Nyungan language bloc. These ancient and distinctive languages cover the Kimberley, Arnhem Land, a small area of the Gulf of Carpentaria and Cape York, and Tasmania (McConvell 1996). There are four major language groups across the Kimberley with between two and nine dialects (AIATSIS 2019):

1. Worrorran: Worara, Wunambal, Gamberre, Miwa, Kwini, Ngarinyin, and Worla
2. Jarragan: Yiiji, Kija, Kadjerrong, and Miriwoong
3. Bunaban: Bunaba, and Gooniyandi
4. Nyul Nyulan: Bardi, Yawaru, Jabirr, Nimanburu, Warwa, Nyikina, Ungumi, Umida, and Unggarangi

All Kimberley rock art was made by people ancestral to these groups. Kimberley rock art and iconography are well-known, particularly Gwion Gwion (formerly "Bradshaw") and Wanjina (also "Wandjina") "styles" or "traditions" that were produced and maintained by Aboriginal people. It is thus both creation and subsequent maintenance that are key to understanding this rock art. For example, Layton's (1992) synthesis opens with Love's image of the Wandjina Namarali (1930), which was repainted between January and March 1929 by Indamoia and Wallamurra and was later reproduced for use by Donny Woolagoodja in the 2000 Sydney Olympic Games Opening Ceremony (Fig. 1).

Throughout this entry, we use Wanjina and Gwion Gwion rock art traditions as leitmotifs that help us better understand the Kimberley's many other forms of rock art.

Historical Background

The Kimberley was never an isolated human landscape, with considerable trade, movement, and contact with the outside world for at least the last few hundred years. Prior to European invasion/colonization, Macassans from Island South East Asia visited the region to harvest *bêche-de mer* (trepang or sea cucumber) along the Kimberley coast for "at least two hundred years" (1803 encounter recorded: Crawford 2001:70, 3) and likely much longer. Crawford (2001) recorded 16 Macassan sites along the Kimberley coast and excavated a selection of these in the 1960s with Aboriginal Traditional Owners. New Macassan sites have just been identified and excavated in 2019 on Sir Graham Moore Island, north of Kalumburu (Paterson, personal communication)

European incursions that document rock art include George Grey in 1837–1838, Alexander Forrest in 1879, and Joseph Bradshaw in 1891. These travelers' inability to reconcile "complex" rock art with people they thought of as "primitive" generated an enduring and mendacious myth of non-Aboriginal authorship of the rock art. For example, Grey writes: "It is certain that they may have been very ancient, ... but, whatever may have been the age of these paintings, it is scarcely probable that they could have been executed by a self-taught savage. Their origin

Kimberley Rock Art, Fig. 1 Namarali Wandjina: 1930 repainting (left: Love (1930), in Layton (1992)) and 2000 Olympic Games use (right: BBC Mundo, bbc.co.uk); with inset map showing the Kimberley's location

therefore I think must still be open to conjecture" (1841: 263). Later, Bradshaw continues this trope by stating "Indeed, looking at some of the groups [of Gwion paintings], one might almost think himself viewing the painted walls of an ancient Egyptian temple" (1892: 100). This pathology of British colonialism is entirely without factual basis and has been successfully challenged by both Aboriginal and non-Aboriginal scholars (e.g., Mangolomara et al. 2019; McNiven 2011).

This "dissociative archaeology" (McNiven 2011) occurred in tandem with dispossession of land for pastoralism from the 1880s as a result of Forrest's expedition. Aboriginal resistance and remoteness combined to make pastoralism largely unviable until the mid-twentieth century (Crawford 2001). Christian missions across the Kimberley, at Kunmunya, Munja, and Wotjalum in the West, and Kalumburu and Pago in the East (Crawford 2001) brought further disruption. However, Europeans also recorded valuable ethnography, including the creation and repainting of rock art from at least 1929 until today (cf. Layton 1992; Love 1930).

Key Issues and Current Debates

We identify four key issues in Kimberley rock art:

1. Time – Relative sequencing and association, as well as direct dating of rock art traditions
2. Space – Spatial distribution of rock art traditions and their relationship to current linguistic and cultural territories
3. Meaning – using both Aboriginal ontologies and archaeological/anthropological research
4. Heritage – management of rock art and related heritage now and into the future

Time: Relative Sequencing and Association

While Aboriginal people know rock art to be produced at both many and all times, "western" science prefers discrete dates and ranges. It has been proposed that Kimberley rock art dates to the Pleistocene, even as far back as initial colonization ~50,000 years ago (Veth et al. 2019). But in the absence of direct dating of rock art for most of the twentieth century, researchers relied on superimpositioning, the construction of "stylistic

sequences" and associating painted motifs with those found in excavations or known ethnographically. We explore these before presenting current and new direct dating evidence.

Two key stylistic chronologies were published almost simultaneously by David Welch (1993) and Grahame Walsh (1994). Welch classified and sequenced by technique, namely, cupules, engravings (petroglyphs), and paintings (pictographs), and by iconographic detail, such as, anthropomorphic body position (i.e., bent knee or straight parts) and attributes (e.g., tassels, material culture), without applying consistent variables between his five "periods" (Archaic, Tasseled, Bent Knee, Straight Parts, Wandjina, Contact: Fig. 2). Walsh's (1994) chronology included three Epochs (Archaic, Erudite, and Aborigine), each with two Periods, namely, "Pecked Cupule"; "Irregular Infill Animal Period"; "Bradshaw (Agnes Schulz of the 1938–1939 Frobenius Expedition first labeled Gwion Gwion as 'Bradshaws' in reference to Joseph Bradshaw publication on the same (1956: 45))"; "Clothes Peg"; "Clawed Hand"; and "Wanjina," some of which has further group subdivisions, each with subdivisions (Fig. 3).

Walsh's (1994) tripartite temporal led him to hypothesize discontinuity between Epochs, which at that point matched apparent site abandonments recorded archaeologically (e.g., O'Connor et al. 1999) – but which recent micromorphological research has challenged, suggesting continuous human occupation of the Kimberley (Travers and Ross 2016) albeit with fluctuating intensity. He linked the two most recent Periods – Clawed Hand and Wanjina – with living Aboriginal culture, but separate from the earlier "Erudite" styles.

In 1999, Walsh and Mike Morwood co-published the known occupation sequences from stratified rock-shelter excavations across the Kimberley – covering the last 42,000 years. This data was combined with observed changes in the art sequence, particularly the superimposition of spears, spear-throwers, and other armatures. For example, early "Tassel Bradshaw" (Gwion

Kimberley Rock Art, Fig. 2 Welch (1993) stylistic sequence

Kimberley Rock Art, Fig. 3 Walsh (1994) stylistic sequence

Gwion) has short spears depicted with an acute barb at one end, and multiple barbs at the other, with no spear-throwers depicted. In the later "Clothes Peg" (Static Polychrome) tradition, new types of spears are depicted, and spear-throwers are present. This builds on Lewis's (1988) key research across Arnhem Land and the Kimberley on style and material culture, confirming that there are patterned changes in technology across identified styles. At about the same time, excavation-centric research in the southern Kimberley produced the oldest known age for pigment applied to rock in the form of a hematite-covered limestone slab excavated at Carpenters Gap. This slab was found in layers dating to 42,700 BP (O'Connor and Fankhauser 2001).

Time: Scientific Dating

Fortunately, while direct dates are technically challenging due to paucity of dateable material within most pigments, (with the exception of charcoal used in, e.g., Wanjina eyes, as well as rare beeswax art (Morwood et al. 2010)), technology has advanced. Over two dozen published, direct dates are now available with dozens more soon to be published (Table 1). At least seven different techniques have been used to date material above or below painted motifs to determine maximum and minimum ages. These include conventional and AMS radiocarbon as well as OSL dating of mud-dauber wasp nests and AMS radiocarbon dating of beeswax. Uranium-thorium dating of mineral crusts and geomicrobiology are also being trialed, while cosmogenic dating of rock slabs is looking more broadly at when rock-shelters formed.

Table 1 provides a summary of dated Kimberley rock art from published sources. Wanjina and Gwion Gwion traditions have, once again, enjoyed particular attention with the former dated to between 5100 ± 240 BP and the present and the latter controversially dated to older than 17,500 ± 1800 (Roberts et al. 1997; Table 1; see Aubert 2012). Ross et al.'s (2016) multi-year research in the Northwest Kimberley used multiple dating techniques, with successful OSL and AMS radiocarbon on fossilized mud wasp nests, returning dates from the terminal Pleistocene into the Holocene. This program questioned the sequential, as opposed to overlapping, nature of styles in Kimberley rock art and highlighted the need for a larger dating program.

Current research is working to refine dates across all traditions, with upcoming publications for Gwion art, to understand the relationship of Gwion Gwion to the inferred older Irregular Infill Animal tradition. Recent presentations of primary data on AMS dates from bracketing mud wasp nests (Finch et al. 2019) suggest that at least some of the complex Gwion Gwion style art is of terminal Pleistocene age (c. 14–12 ka). Understanding temporal contexts helps us to make spatial sense of Kimberley rock art traditions.

Space: Distribution of Rock Art Traditions and People

When these different rock art traditions are mapped onto the extant Kimberley landscape today, interesting trends emerge. Figure 4 shows the spatial distributions of three key traditions: Gwion Gwion, Static Polychrome (Clothes Peg figure), and Wanjina. While there is significant overlap of all three traditions, Gwion Gwion motifs have the most restricted distribution – albeit with an eastern outlier in the Keep River region of the Northern Territory, where Static Polychrome figures are more dominant. Wanjinas have the most southern distribution and may connect to desert areas.

Veth et al. (2018) revised the temporal and spatial sequence, matching the six macro-styles (Pecked Cupule; Irregular Infill Animal, Gwion Gwion, Static Polychrome [Clothes Peg], Painted Hand, and Wanjina) with archaeological and environmental evidence across a 50,000 year chronology (Fig. 5). This work used 3750 rock art sites across the Kimberley – with the greatest concentration in the central and southwestern Kimberley as recorded by Walsh, and built upon by current research projects and housed in the Takarakka and *Kimberley Visions* project databases. This work also tracked the prevalence of plant motifs, often identifiable to species, across traditions (Veth et al. 2018). Plant motifs include grasses, trees, tubers, human-plant conflations, and plant-based material

Kimberley Rock Art, Table 1 Published Kimberley rock art dates

Style	Date (CalBP)	Method	Sample	Material	Description	Reference
Gwion Gwion	17,500 ± 1800	OSL	KERC5	Quartz grain	Adjacent to Gwion motif (KERC4)	Roberts et al. (1997)
Gwion Gwion	16,400 ± 1800	OSL	KERC4	Quartz grain	Directly over Gwion motif	Roberts et al. (1997)
Wanjina	5100 ± 240	OSL	LM-13	Quartz grain	Macropod	Ross et al. (2016)
Gwion Gwion	3880 ± 110	AMS	CB3	Mineral crust	"Cane Bradshaw"	Watchman et al. (1997)
Wanjina	3780 ± 60	AMS	OZC434	Beeswax	12 × 10 cm Wanjina head	Watchman et al. (1997)

culture such as digging sticks, dilly bags, hafted axes, spears, spear-throwers, and boomerangs. Plants are also represented directly via direct grass "prints." This work establishes the likelihood that the Kimberley houses some of the oldest depictions of plants in the world, with examples from both IIAP and Gwion traditions, which are thought to be Pleistocene in age, and continuing also into the most recent art traditions. This work moves us away from static understanding of past Aboriginal people as "hunter-gatherers" or "foragers" and explores human manipulation of plant resources over millennia in a complex people-plant relationship described as "eco-scaping" (Ouzman et al. 2017).

Interestingly, at both the center and on the edges of the Kimberley, a number of traditions have been identified that do not fit within existing style sequences. In addition, the southeastern Forrest River art styles (Kaberry 1936) share similarities to Keep River region and other desert fringe art styles. Indeed, the linkages of rock art

Kimberley Rock Art, Fig. 4 Key Kimberley rock art traditions' distributions. (Modified from Walsh 1994)

traditions with other areas may occasion us to rethink and redefine what we mean by the "Kimberley" – especially when realizing a great deal of what would have been human-occupied land is now underwater.

Here "contact" rock art provides instructive examples. While not as prolific as in Arnhem Land (May et al. 2010) or the Pilbara (Paterson and Wilson 2009), it includes "new" imagery such as boats (European and Macassan), cars, camels, horses, and European clothes (O'Connor and Arrow 2008; O'Connor et al. 2013; Ross and Travers 2013). There are also new production techniques for "old" imagery, such as scratching and use of charcoal to produce anthropomorphs with elaborate headdresses (O'Connor et al. 2013). Interpretation of contact art has focused on identification and antiquity of boats (Akerman 2015; Ross and Travers 2013) and the creation of art as an act of resistance during the contact period, mostly since the 1820s (O'Connor et al. 2013). However, not all boat imagery was created during the contact period (Akerman 2015; Ross and Travers 2013; Walsh 1994), as there are a series of canoes painted in Gwion Gwion scenes, suggesting great antiquity. This broad temporal and spatial sweep allows us to better understand possible meanings for these rock art traditions.

Meaning: Aboriginal Ontologies and Archaeological Research

This expanded understanding of the Kimberley, and utilization of multiple data sets – rock art, archaeology, ethnography, and paleoenvironment – productively disproves and displaces early interpretations of Kimberley rock art by outsiders as simplistic or even non-Aboriginal in origin. Indeed, a key development in Kimberley rock art

ROCK ART STYLE DISTRIBUTION	MAJOR IDENTIFYING ROCK ART ELEMENTS
1. PECKED CUPULE 	Sites have pebraded cupules, abraded grooves and in 25% of instances grinding hollows in association. Surface modification may indicate vegetable/animal and ochre processing. Positive print pigment grass seed stems and heads may be in association.
2. IRREGULAR INFILL ANIMAL 	25% of sites depict yams and a variety of other flora with leaf, flower and root details. Grass imprints are depicted in 38% of sites containing plant motifs. Less common are prints of string and feathers. Aquatic species dominate, mostly fish and long-necked tortoise.This style also includes birds, echidnas, snakes flying possums, flying foxes, possums, and macropods. Extinct species present. Anthropomorphs are rare and include Mythological beings.
3. GWION 	2% of sites have plant motifs. Highly decorated human figures are dominant. Early 'tassel' figures hold sticks, dillybags, palms and fern leaves. Figure style changes to 'sash', long plumes, pompom, feathers. Later figures hold multi-barbed spears, macropod hunting scenes and therianthropes are depicted. Stylised figures lose leg detail with some decorated with plant-like motifs.
4. STATIC POLYCHROME 	4% of sites have plant motifs, painted with very fine lines and most are botanicals. Human figures also dominate. Figures are polychrome with missing pigment. Headdress styles are very diverse with added features such as tussocks and tassels. Multi-barbed spears, spear throwers and conflict scenes are evident. Macropods most common fauna. Large watercraft are depicted.
5. PAINTED HAND 	18% of sites have plant motifs, mainly yams, scenes of yams and people and anthropomorphised plants. Diverse range of paintings encompassed in this period. Early figures are painted with broad strokes and develop into decorative compartment body detail. Anthropomorphs depict gender, ritual practices and social aggregation. Macropods, crocodiles, lizards, birds, turtles,and echidnas are common. Motifs include concentric circles and decorated hands with distinct nails.
6. WANJINA 	19% of sites have plant motifs. Early plant motifs are naturalistic while later art is more stylised and symbolic. Fruit is depicted as groupings of circles. Figures are (named) ancestral beings, controllers of the elements. When Wanjina art is repainted and cared for it brings rain and the regeneration of food and a range of other life processes. Dingo paintings enter the art, and the Thylacine is no longer depicted. Yam and animal themes replace older figurative art with the later re-appearance of argula 'devil' figures and ritual practice.

Kimberley Rock Art, Fig. 5 Revised stylistic chronology and plant motif distribution (Veth et al. 2018)

K

research in the later twentieth century is the increasing coexistence of Aboriginal ontologies alongside archaeological research (Porr and Bell 2012).

For example, the Kimberley is in an instructive position with regard to the Wanjina – a broad cultural practice embodied in a rock art that is at least 5000 years old and which continues today (Akerman 2016). The late David Mowaljarlai characterized Wanjina thus:

> To us they are IMAGES. IMAGES with ENERGIES that keep us ALIVE. Those IMAGES were put down for us by our Creator, Wandin. So that would make us learn the story, to put new life into those IMAGES (1988: 690; see also Elkin 1930; Shulz 1956).

Wanjina cosmology is exceptionally rich: it weaves art, ochre, rain, and regeneration into a complex and integrated worldview. Wanjina country is traditionally within the Worora, Wunambal, and Ngarinyin language group, divided into patrilineal clan estates which were each responsible for Wanjina sites and their maintenance (Akerman 2016). Wanjinas are known as individuals named and associated with specific sites, events, and heroic actions. Wanjina is closely linked with Ungud, the serpent, but their relationship varies from the west to the east Kimberley. Recent excavation of Borologa rock-shelter on the Drysdale River in the northeastern Kimberley has revealed three Wanjina painting episodes over the last 2000 years, as evidenced through recovered ochre fragments and paint drops recorded in situ during meticulous excavation (David et al. 2019). This research highlights that stylistic and spatial variation through time is yet fully to be understood.

Such successive painting episodes intensify into the practice of retouching Wanjina images, which was recorded by Love, Elkin, and Crawford. Godden noted that on seeing a faded Wanjina at the site Wumbadengari, the senior Aboriginal men Mowaljarlai and Jagamurro would return to paint the site, once "*they had received proper permission from the old men and women*" (1982: 24). More controversially, David Mowaljarlai was involved in a government-funded repainting program in 1986 (Layton 1992; Mowaljarlai et al. 1988; Mowaljarlai and Peck 1987; Utemorrah and Vinnicombe 1992). Debate arose around this particular repainting program, an official complaint submitted by a non-Aboriginal pastoralist and labeled "defacement" by the Australian media (Bowdler 1988). These criticisms perpetuated a static view of Aboriginal culture, promoted rock art as a pristine relic, and removed agency of Aboriginal people and ownership of their living culture.

In the east Kimberley around Forrest River, a different kind of repainting was recorded by Kaberry (1938), with repainting on crocodile motifs recorded as an increase ritual for that animal. Additionally, Kaberry records women artists on this side of the Kimberley but highlights potential rich work in researching gendered aspects of rock art.

It is important also to understand "rock art" as not being restricted to a rock-shelter but transferring across media. For example, Wanjina is also associated with standing stones, which are understood to be transmogrified Wanjina called *djilgaiya* by the late Sam Woolagoodja (Layton 1992). Such transmogrification relates closely to Wanjina as living entities with close parallels to human life and form. Here, Adolphus Elkin's early but oft-overlooked research in the 1930s identified features in Wanjina art such as the headbands, hair, hair belts, and associated features such as lightning or cockatoo feathers (Fig. 6).

Material Culture and Dance

This focus on the human body and close relationship between rock art, the people and agents who made it, and performativity is continued further back in time with Gwion Gwion paintings. David Welch's intriguing observation that Gwion Gwion material culture and accouterments – despite their likely Pleistocene age – are strikingly similar visually to ethnographically recorded Kimberley material culture (2015: 219) merits further examination, for example, ethnographic photographs of Kimberley men dancing with *ngadari* headdresses and carrying spear-throwers and bunches of leaves and feathers remarkably similar to those shown in the rock art (Fig. 7). But rather than relying on

Kimberley Rock Art, Fig. 6 Wanjina at Beleguldo (Modum) (Elkin 1930)

Kimberley Rock Art, Fig. 7 Kimberley men dancing with *ngadari* headdresses (Welch 2016)

direct ethnographic analogy as an analytical approach to explain the connection between these headdresses, accouterments, and the rock art, this deep time rock art repetition of motifs sees longer-term persistent behaviors of social reproduction. These persistent themes through varying traditions likely reflect long-term connections to country, cohesive group identities, and the cultural transmission of clan and linguistic affiliations. These social relations were dynamic as sea levels rose, climate fluctuated, and environmental landscapes shifted (Veth et al. in press).

Heritage: Managing Heritage and Change

We have used both ancient and modern Kimberley rock art to illustrate the rock art's enormous temporal, spatial, and ontological scope. But simply understanding this art is not enough – it has to be actively managed and made known to the world.

Kimberley Rock Art, Fig. 8 Kimberley Ranger Network (KLC 2017)

Following successful native title determinations since 1992, the Kimberley is today dominantly Aboriginal owned with over 84% of it and managed through large Indigenous Protected Areas (IPAs), Aboriginal Corporations, and affiliated Aboriginal ranger programs (Fig. 8). There are 70 full-time rangers in 13 ranger groups (Balanggarra, Bardi Jawi and Bardi Jawi Oorany, Dambimangari, Gooniyandi, Kara Jarri, Kija, Ngurrara, Yimardoo Warra [Nyikina Mangala], Nyul, Paruku, Uunguu, and Wunggurr rangers. There are also non-Aboriginal pastoral and tourism leases and government land. While the history of dispossession, relocation of people, the missions, and the current variety of tenures have all had an impact on Aboriginal access to traditional lands and cultural sites, there is an active program of reconnection to country in which rock art plays a key but as yet not fully realized role.

International Perspectives

The Kimberley presents one of the world's largest multi-style rock art bodies that stretches back at least 40,000 years and which remains connected to modern Aboriginal people today. This rock art coexists with rich archaeological, ethnographic, and paleoenvironmental data that has only been scientifically explored over the last few decades, promising new and ongoing research findings that will inform us of rock art's role in managing social and environmental change.

Future Directions

Future directions for Kimberley rock art research include the continued direct dating of rock art across traditions and regions. More work needs to be done contextualizing rock art and other symbolic markings and structures with subsurface archaeology. Especially exciting are nascent indications of how people and rock art connected across northern Australia and into Southeast Asia, which we now describe.

Rock art was most likely a key element in the colonizing repertoire of the First Australians, providing us with detail on the type and timing of their move into what was then the Sahul landmass. The visual and contextual similarities between Kimberley rock art and that recorded and dated

in Borneo, Sulawesi, Timor, and New Ireland, between 50 and 42 kya, provide evidence of people overcoming sea barriers with purposeful voyaging, having mixed terrestrial and marine economies and possibly sharing symbolic systems. Aubert et al. (2014) reported a 40,000 year old babirusa (deer-pig) rock painting from Sulawesi, which has stylistic similarities to the Irregular Infill Animal tradition of the Kimberley, including a thick outline, naturalistic representation of the faunal features, and irregular economic use of pigment infill. The same research team have presented the Datu Saman figures from Borneo (Aubert et al. 2018), dated to older than 13.6 years ago, and these anthropomorphs share some similarities to Kimberley Gwion Gwion as well as Arnhem Land's dynamic figures in being dark red, fine-line, dynamic, with elaborate headdresses and holding material culture. There is also a shift from naturalistic animal to human figures and material culture, as is also seen across northern Australia. These stylistic similarities suggest permeability across a potential trans-Wallacean culture bloc around 50,000 years ago, probably reflecting the region as a "hot spot" for island and continental dispersal. These shared styles suggest long-distance transmissions, between maritime and tropic-adapted peoples, and that at least some of these transmissions continue well after continental colonization on either side of the Last Glacial Maximum (Veth et al. in press) More fine-grained research, currently being developed, across northern Australia and Wallacea will further develop this model for (inter)tropical adaptations and cultures with their own strong "imprints" on country.

Moving to northern Australia per se, Darrell Lewis (1988) first suggested that the now submerged Bonaparte catchment culturally connected the Kimberley and Arnhem Land. He recognized that at the height of the Last Glacial Maximum (~19,000 years ago), the Pleistocene coastline would have been hundreds of kilometers north of its current iteration. Additionally, Gwion Gwion and Elegant Action figure traditions of the Kimberley show marked stylistic and material culture correspondences with Arnhem Land's dynamic tradition rock art, which is also thought to be Pleistocene (May et al. 2018). These similarities suggest an older, more unified cultural bloc that used rock art to signal a common identity, which then evolved over time into more specific place-based adaptations and signalings.

Conclusion

Kimberley rock art is best understood using multiple analytical lenses to account for the enormous variation in time, space, and cultural range. Kimberley rock art research provides an ideal model for twenty-first century science in that it is empirically rigorous, enmeshed in paleoclimatic and paleoenvironmental frameworks, and socially responsive, working with Aboriginal custodians and two-way learning. Research directions are negotiated within this milieu, along with multiple ontologies, needs, ethics, and aspirations.
